## **Lecture Note on Internet & Web Technology Diploma 3<sup>rd</sup> Year (5<sup>th</sup> Sem)**

**BRANCH-CSE**

*Prepared by: - Ms. Monali Patel  
Senior Lecture*

***Computer Science & Engineering***

→ devices like smart phones, desk top etc.

HTML (Hyper Text Markup Language)

→ It is a language which works with the help of tags.

→ This language is used to design a webpage

→ The HTML page has 3 sections

1) HTML

2) Head

3) Body

→ created by Tim - Berners

Lee, Robert Cailliau in 1989

→ The HTML part is the default one for any webpage.

→ The Head part consists of the head area, title etc. The head part is not compulsory in a page.

→ The Body part is the most essential & compulsory area in HTML.

→ It consists of the codes which are used to design the web page.

Tag

→ Tags are the program coding code that are used for program coding to design a webpage

In html there are 2 types of tags

a) Paired tag

b) Single tag

→ The paired tag are the tags which are used with pairing

eg: `<html> </html>`, `<body> </body>`

→ Single tag are the tag that can be used without any paired tag

eg: `<br>`

→ next line

The tag has its own attribute an value. Each & every tag has diff. attribute with different value. This attribute & value can be used according to user requirement with in the tag

eg: `<Body bgcolor = "Blue">`

↓	↓	↓
Tag	Attribute	value
name		

Designing a web page

The html follow the syntax to write the code for the

web page, the standard syntax is as follows

<html>

<head>

<title> Name of the title </title>

code

</head>

<body>

code

</body>

</html>

Hyper text ⇒  
links that allow the  
reader to jump to  
other places.

Markup lang.

→ computer  
speak to  
each other

to control how  
text is shown

eg:-

<html>

<head>

<title> welcome to my page </title>

</head>

<body>

<B>

This is my 1st webpage </B>

</body>

</html>

</html>

<body background = "path of the image">

This is my 1st webpage

</body>

<body>

<Font type = "monotype cursive">

size = 5 </Font>

<B> This is my web page </B>

</B>

</Font>

How is yours. </Font>  
</Body>

<Body align = "center">  
</Body>

Design a web page, that display your  
Biodata as follows

Name:	
Gender:	
Address:	
Phone:	

<html>

<head>

<title> BIO-DATA </title> </head>

<marquee behaviour = "scroll" direction = "right">  
<Font color = "yellow" Font face = "times new roman"  
Font size = "14">

WELCOME TO MY PAGE </Font>  
</marquee>

<body background = "E:\Wallpaper\cma.jpg"  
width = "1000">

< Font size = "6.5" Font color = "white"  
Font Face = "times new roman" width = "500"  
height = "300"> < br>

< center>

NAME: Monali Patel < br>

GENDER: Female < br>

ADDRESS: Tsg < br>

PHONE: 9078165070 < br>

< / center>

< / Font>

< / body>

< / head>

< / body>

< / html>

DT- 15.12.17

Formatting

the text

A text in a html page can be format using the Font tag.

→ The Font has the following attribute

1) Type

2) Size

→ The Font type is the diff. type of

style & the Font size is from 1 to 7

→ To make a text bold we have to

use < B > tag to make a font

Italic we have to use < I > tag

to make a font underline we can

use < U > tag & < U > underline < U >

eg:- We can highlight a tags text by underlining the text by making it a head line. the headline text can be done by using H1 to H3 tag

eg:- `<H2>` This is a heading `</H2>`  
`<H3>` I am also a heading `</H3>`

HR tag  
 ↳ Horizontal line

→ The `<HR>` tag insert a line to separate a section.

#### - Alignment

We can centrally place any object with in a html page using the `<center>` tag this is a paired tag & can be written as

`<center>` `<font type="Arial">` `</font>` `</center>`  
 This is center

`<center>` `` `</center>`

#### List

There are 2 types of list in html

a) unordered list  
 b) ordered list

eg:-  
 • megha  
 • Patel  
 • monali

• A. Socket  
 • B. Servlet  
 • C. Mail API

`<LI>` → List  
`<UL>` → unordered list  
`<OL>` → ordered list

eg:- `<UL type="list-style-type: none">`  
 • `<LI>` megha  
 • `<LI>` Patel  
 • `<LI>` monali  
`</UL>`

or  
 • megha  
 • Patel  
 • monali

`<OL type="1" start="5">`

`<LI>` megha  
`<LI>` Patel  
`<LI>` monali

<html>

<head>

<body>

<font size = "5" font face = "Times New Roman">

<center>

Vikash Institute of Technology, Bangarch

4th Semester VST Examination-2017<br>

DATABASE SYSTEM<br>

BRANCH(S): CSE<br>

Time: 3 hour<br>

Max. marks: 100<br><br>

Answer question no. 1 and no. 2 which is compulsory and any four from the rest.<br>

The figures in the right hand indicates marks.<br>

</center>

<ol type = I>

<li> Answer the following questions:

</ol>

<ol type = 1>

<li> which of the following is not a Armstrong's Axioms?

</ol type = a>

<li> Reflexivity rule </li>  
 <li> Transitivity rule </li>  
 <li> Pseudotransitivity rule </li>  
 <li> Augmentation rule </li>

</ol>

</ol>

</font>

</body>

</head>

</html>

①

01-16-12-17

Adding graphics to the html

We can insert a picture in a page by using <img> tag.

The <img> has following attributes

1) src :-

Source of the image (path)

2) border

3) Height

4) Width

5) alt :- give a description about the

image when an image is pointed by

mouse pointer

eg:- <html>

<body>

```

<img src = "c:\desktop\abc.jpg" height = 200
width = 200 alt = "a Flower" border = 4>
</img>
</body>
</html>

```

align = right

Inserting table in html

table

```

<html>
<table>

```

```

<tr>

```

```

<th>

```

```

</th>

```

```

<tr>

```

```

</tr>

```

```

<td>

```

```

</td>

```

Table  
row

✓

Name	Sub	mark
XYZ	math	51
abc	Hindi	21

DT-18.12.17

cellpadding

We can align the text of a cell

within the table using the align attribute. The cellpadding is used to padded the content of the text.

```

<table border = 3 cellpadding = 10 align =
center>

```

```

<tr>

```

```

<td> x </td>

```

<TD> Y </TD>  
</TR>

</TR>

<TD> Z </TD>

<TD> M </TD>

</TR>

</Table>

cellspacing  
<Table

border = 3

cellspacing = 10 align = center

<TR>

<TD> X </TD>

<TD> Y </TD>

</TR>

<TR>

<TD> Z </TD>

<TD> M </TD>

</TR>

</Table>

Bgcolor

<Table border = 3 cellspacing = 10 align = center

bg color = "Blue">

<TD bgcolor = red> X </TD> <TD> Y </TD>  
individual cell

<tr bgcolor = blue> <font color = red> X  
 </font> </tr>

student details

Regd- No	Name	Mark		
		Sem-1	Sem-2	Sem-3

colspan & Rowspan

<table border = 3>  
 <caption = student details> </caption>

<tr>  
 <th colspan = 5>

<th rowspan = 2> Regd-No. </th>

<th rowspan = 2> Name

<th colspan = 3> Mark

</tr>

<tr>

<th> Sem-1

<th> Sem-2

<th> Sem-3

</tr>

<tr>

<td> 1501337021

<td> Monali

<td> 21

<td> 25

<td> 29

</tr>

<html>

<table border = 3>

<caption> Train details </caption>

<tr>

<th rowspan = 2> Name of the train

<th rowspan = 2> place

<th rowspan = 2> Destination

<th colspan = 2> Time

<th rowspan = 2> Fare

</tr>

## Linking Document

We can link a document or page from one html page. This is called hyperlinking. The hyperlink appears blue in color. We can make an image as hyperlink. The hyperlink text is having default color. The default color is blue & visiting color is pink. To make a text link to a page the syntax is -

eg: `<A HREF = "biodata.html"> click here to biodata </A>`

`<html>`

`<body>`

`<A href = "c:\desktop\table.html">`

`<img src = "c:\flow.jpg"></img></A>`

`</body>`

`</html>`

## Property

`<a href = "#css">css</a>`

## Frames :-

By using the frame we can split the browser screen into several section according to our requirement.

→ These frames can be creating using the `<Frameset>` tag.

→ It is paired tag. This tag has the attribute of rows & cols is rows property.

eg:- `<Frameset rows = "33%, 33%, 33%">`

`<Frameset cols = "50%, 50%">`

`</Frameset>`

`<Frame>` tag

Frame is a tag which define each

Frame on the screen.

→ It has the following attributes

1) src :-

`src <Frame src = "intro.html">`

2) Margin width

`<Frame margin width = "n" height = "m">`

3) `<margin width = "n">`

4) Name

5) ~~No resize~~ Noresize

6) scrolling = Y/N

eg:-

```
<html>
<frameset rows = "10%,*">
  <frame src = "header.html" marginheight=0
    marginwidth = 0 name = "Frame1">
  <frameset cols = "35%,*">
    <frame src = "scfamil.html"
      name = "Frame2">
    <frame src = "disc.html" name = "Frame3">
  </frameset>
</html>
```

heart.html

```
<html>
<body background = ".../.../image/textures.gif">
  <font face = "comic sans ms">
    <center>
      <h2>The scf family</h2>
    </center>
  </body>
</html>
```

scfamil.html

```
<html>
<body background = ".../.../images/textures1.gif">
  <br>
  <br>
```

```
<center>
```

```
<img height = 157 width = 150
```

```
src = "SCTFAMIL.gif">
```

```
</center>
```

```
</body>
```

```
</html>
```

desc.html

```
<html>
```

```
<body background = ".../.../image/texture1.gif">
```

```
<B><br><br>
```

```
<UL>
```

```
<LI> Mr Inan Bayross
```

```
<LI> Mrs. Adyasha Mishra
```

```
<LI> Monali Patel
```

```
<LI> Payal Agrawal
```

```
<LI> Seema Baghel
```

```
<LI> Priyanka Sahu
```

```
</UL>
```

```
</B>
```

```
</body>
```

```
</html>
```

```

<html>
<body>
<form>
  user ID <input type="text" Name="Mon"
  Patel value=" " /> <br>
  Password <input type="password" Name="Pas"
  value=" " /> <br>
  <input type="checkbox" Name="checkbox" value=" " /> Remember
  <input type="button" Name="button1" value="Sign in" />
  &nbsp; <input type="button"
  Name="button2" value="Sign out" />
</form>
</body>
</html>

```

## cascading style-sheet (CSS)

01-01-18

- 'style sheets' are the mechanism which makes the html page dynamic & powerful.
- The style sheet adds style such as font, color etc.
- The style sheet enforce standard & uniformity through out a website & provide numerous attribute to create a dynamic effect.
- By using the CSS the properties of style can be defined in a single list.
- The advantage of style sheet includes the ability to make global changes to all document from a single location.
- In html page the style can be defined with the tag `<style>...</style>`.
- The `<style>` tag are written within the `<head>` tag.
- Syntax:
 

```

<style type="text/css">
  tag { font: ..... }
  :
  :
</style>

```

## Cascading Style Sheet : $\Rightarrow$ CSS

~~HTML~~

$\hookrightarrow$  HTML creates structure of our webpage

But, CSS turns our boring looking HTML web pages to good looking website.

$\hookrightarrow$  CSS is optional but it is impossible to create website without using HTML.

CSS  $\Rightarrow$  different icons / Navigation

$\hookrightarrow$  Website/web pages by using only HTML looks messy. (But CSS works)

Version of CSS :  $\Rightarrow$  (Hakon Wium Lie)  
in 1994

• 1996 :- CSS 1

• 1998 - CSS 2

• 1998 - Started working on CSS 3 (current version)

$\hookrightarrow$  divide into diff. modules

CSS code :  $\Rightarrow$

<html>

<head>

<title> Different ways to apply CSS </title>

<head>

<body>

<h1> + leading </h1>

</body> </html>

Normal HTML code

35,51,77

\* How to write CSS code?

a) inline attribute  
→ using the style attribute in HTML elements  
Apply in single tag

```
<h1 style="color: green;">Heading</h1>
```

b) style tag before <body> & after

```
head. | internal CSS → using <style>  
element in the <head>  
section.
```

```
<head>  
<title> ... </title>
```

```
<style>  
h1 {  
    color: green;  
}
```

for  
whole  
(same style)

```
</style> </head>
```

```
<body> <h1> Heading </h1>
```

```
</body>
```

c) External file CSS code

→ using .css file  
→ Different code file for CSS & HTML

```
style.css
```

external

```
h1  
{  
    color: green;  
}
```

## • html

→ we have to link css file to html b/w that use <link> tag.

<head>  
<link rel = "stylesheet" href = "style.css" ⇒ Reference link  
</title> ... </title>

</head>  
<body> <h1> Heading </h1>

## \* For all css file

→ create new folder (css)  
& store all under this folder  
& give path of that folder

to href

css color :- /\* \*/

color: rgb(—, —, —);

hexcode #FFA53d; → color picker

background-color: —;

Font : →

~~css~~

body {

Font-Family: Arial;

}

mehan

\* → we can import any font from google

↳ select font

↳ select style

↳ Embed

↳ link (copy)

• html

paste after link

↳ css rule

paste to css file

Font-weight

or @import

↳ under <style> tag & paste it in to

css before body { }

Sub/combinator Selector :-

a) Descendant Selector

b) child Selector

c) General Sibling Selector

d) Adjacent Sibling Selector

a) Descendant Selector :-

<head>

<style>

`ol <sup>space</sup>li { background-color: yellow; }`  
`</style>` descendant selector  
`</head>`

`<body>`

`<ol>`

`<li> item 1 </li>`

`<li> item 2 </li>`

`<ul> <li> sub item 1 </li>`

`<li> sub item 2 </li>`

`</ul> <li> item 3 </li> </ol>`

`</body>`

// all are child of  
 'ol' type

c direct/indirect

↓  
 css apply  
 in all

b) child selector:-

$\rightarrow$   
 symbol

$\Rightarrow$  Apply only on direct  
child element

`ol > li`

c) Adjacent sibling selector

~~parent~~ `<head> <style>`

$\rightarrow$  target  
`<h1> { background-color: yellow; }`

`</style> </head>`

`<body>`

`<p> para 1 </p>`

`<h2> Heading 1 </h2>`

`<h2> Heading 2 </h2>`

`</body>`

+  
 adjacent  
 immediate

Me & Hall

# d) General sibling selectors

p ~ h1

## CSS Basic Properties:-

- i) Text properties
- ii) List properties
- iii) Borders properties
- iv) Font properties

### i) Text properties:-

<u>Property</u>	<u>Description</u>	<u>Values</u>
color	→ Sets color of a text	RGB, hex, keyword
line-height	→ distance bet <sup>n</sup> lines	no., normal, length, %
letter-spacing	→ increase/decrease space bet <sup>n</sup> character	normal, <del>left</del> right, center
text-align	→ Align text element	left, right, center, justify
text-decoration	→ Add decoration	none, underline, overline, line through
text-indent	→ Indents the first line of the text	length, %
text-transform	→ controls the letters in an element	none, capitalize, uppercase, lowercase

## ii) List property

property	Description	values
list-style	Sets all the properties for a list in one declaration	list-style-type list-style-position list-style-image
list-style-image	Specifies img as the list item marker	URL, none, inherit
-position		inside, outside, inherit
-type	all list item markers	

class When designing a webpage some paragraph may need to look different from other paragraph.

eg :- Think a question & answer page where question is in bold & answer is in plain text.

→ The style sheet supports class of a class can be define to change the style in a specific way for any element it is applied to, a class can be used to identify logical sets of style changes that might be different from any HTML elements.

```

<html>
<head>
  <style>
    p { font-size: 12pt; type: consive; face: bold }
    • question { color: brown; font-style: italic }
    • answer { color: black }
  </style> </head>
<body>
  <p class = question> How do u feel </p>
  <p class = answer> Good </p>
</body> </html>

```

### Multiple Style Sheet : ⇒

⇒ If some properties have been defined for the same selector (element) in different style sheets, the value from the last read style sheet will be used.

eg

```

h1
{
  color: Navy;
}

```

(external style sheet)

```

h1
{
  color: orange;
}

```

internal style sheet

order matters in multiple style sheet

Cascading order:  $\Rightarrow$

- External  
 $\hookrightarrow$  completely separate file with a .css extension
- on page / Internal  
 $\hookrightarrow$  `<style>` tags with css added to the html page within the `<head>` tags
- inline  
 $\hookrightarrow$  adding css as an attribute directly to individual tags with `style = ""` syntax

Cascade order:  $\Rightarrow$  'inline' css overrides 'on page' css which it then overrides 'External' css in the case of conflicting css declarations.

\* NOTE:  $\Rightarrow$  If the link to the external style sheet is placed after the internal style sheet in html `<head>`, the external style sheet will override the internal ss

# CIDR (classless Inter Domain Routing)

↳ comes into existence in 1993 after classful addressing.

↳ 5 classes (flexibility problem)

⇒ No classes

→ only blocks (x amt. of IP address)

↳ based on user demand  
how many blocks they  
wanted.

⇒ ~~in a classful addressing~~

↳ If a company wanted to be connected to the internet  
it had to choose an IP address from the  
appropriate class. For each class, different no. of  
octets (numerical block of IP address) were identified  
to the n/w.

⇒ Class A n/w could accommodate over 16 million  
hosts, but only 128 n/w are available. So on  
for many companies a n/w within 254 participants  
was too small, but several 1000s of hosts need  
the bigger n/w. This ultimately led to a lot  
of waste.

(n/w) → not fixed

## Notation

x.y.z.w / (N) → mask (continuous 1)  
no. of bits, represents blocks/  
⇒ to (no. of n/w).

200.10.20.40 / 28 → n/w id

$$32 - 4 \quad 32 - 28 = 4 \text{ bit (host + id)}$$

Network ID: ⇒ Identify which n/w you're on  
 $4 \times 2^4 = 16$

Host ID ⇒ Device that has an address on the n/w (Router).

28 → continuous 1

11111111.11111111.11111111.11110000

255.255.255.240 ← Mask of the n/w

How to find n/w ID

200.10.20.40 / 28

N/w ID can't be

200.10.20.

change

40 ⇒  $\frac{00101000}{\textcircled{4}}$

00100000 ⇒ 32

200.10.20.32 / 28 ⇒ n/w id

255.255.255.240

& 200.10.20.40

~~255.255~~

\* No. of host?

Network of the id addresses?

## Rules

⇒ Addresses should be contiguous

200. 10. 20. 32

33

34

35

→ No. of Address in a block must be in power

of 2

→ First address of every block must be evenly divisible with size of blocks.

200. 10. 20. 32 / 28

$$2^0 = 16$$

⇒ least significant value is 0,

00100000

ISP (Internet Service Provider) ⇒

ISP is a company that provides web access to both ~~we~~ business & consumers.

→ ISP may also provide other services such as email services, domain registration, web hosting & broadband services.

→ ISPs make it possible for their customers to surf the web, shop online (e-commerce), conduct business & connect with family & friends.

Internet facility

Technology  
ISP:  $\Rightarrow$  modem, dial-up, DSL, cable, broadband, wifi etc

## Types of ISP

- a) Tier 2 ISP:  $\Rightarrow$  provide internet facility globally through sea link  
 $\Rightarrow$  :- Jio, Vodafone, Airtel etc M. Patel
- b) Tier 1 ISP:  $\Rightarrow$  ~~provide~~ for all over the <sup>world</sup> Sha  
world (AT & T, VCNL, Taty)
- c) Tier 3 ISP: - block, colony, etc.

## How it works?

Internet Hubs, Router, Wifi

Public wifi

cellular data

## Types of int

Narrow band  $\Rightarrow$  Data transmission in kbps

Broad band  $\Rightarrow$  multiple data send (both send & receive) at a time  
Speed  $\Rightarrow$  mbps, gbps

## Internet connectivity

The term "internet connectivity" refers to the way people are hooked up to the internet  
 $\Rightarrow$  dial up telephone line, broadband connection, & wire less connection.

at Dialup connection: →

- uses the facilities of the public PSTN.
- establish a connection to an ~~int~~ ISP.

## Internet & WWW

→ Internet is the global data comm<sup>n</sup> system.

→ WWW is a repository of common resources  
i.e. can be accessed by internet.

→ It was started at the European org<sup>n</sup>  
for nuclear research lab, Switzerland.

→ In 1990, Lee developed all the WWW.

HTTP 0.9, HTML, web browsers,

→ HTTP servers & first website name is

http://info.cern.ch & first web browser

name is Mosaic

## Packet Switching

The packets are no. so they can be reassembled  
in the correct position at the destination.

→ The packets are transmitted over the net as capacity  
become available.

→ The packets are routed separately &  
may not follow same route.

→ It is a philosophy of net comm<sup>n</sup>

at Dialup connection: →

- uses the facilities of the public PSTN.
- establish a connection to an ~~int~~ ISP.

### Internet & WWW

- Internet is the global data comm<sup>n</sup> system.
- WWW is a repository of common resources  
i.e. can be accessed by internet.
- It was started at the European org<sup>n</sup>  
for nuclear research lab, Switzerland.
- In 1990, Lee developed all the comm<sup>n</sup> protocols  
http 0.9, html, web browsers.
- http server & first website name is  
http://info.cern.ch & first web browser  
name is Mosaic.

### Packet Switching

- The packets are no. so they can be reassembled  
in the correct position at the destination.
- The packets are transmitted over the net as capacity  
become available.
  - The packets are routed separately &  
may not follow same route.
  - It is a philosophy of net comm<sup>n</sup>.

## Bandwidth

⇒ It is used to measure the speed of internet  
i.e. Kbps, Mbps, Gbps.

→ It is divided into 3 types

i) ~~at~~ broadband → 10mbps

ii) Narrowband → 1-10mbps

iii) Midband → 1-10mbps

Webpage : ⇒ It is a document created using HTML

i) Static Webpage :— Pages will remain same until someone changes it manually.

eg :— About us, mission, vision etc.

ii) Dynamic Webpage :— contents of pages are different

eg :— calendar

Hyperlink :—

Item like word or button that points to another location.

Website : ⇒

Set of webpages which are related,

with a common domain name & IP address.

Webserver : ⇒

→ A website is hosted on a machine is called web server.

→ The webpages on a website are accessed using URL.

Web appl<sup>n</sup> : →

These are the appl<sup>n</sup> that are accessed via web browser usually through n/w.

eg :- Word processor, online spreadsheet & presentation tools.

HTTP :-

→ It is a protocol used to access the data on n/w.

→ HTTP is used to transfer the data, in form of plain text, hyper-text, audio, video & so on.

URL

→ Resource in the web identified by an address called URL.

Internet connectivity :-

The term "Internet connectivity" refers to the way people hooked up to the internet, which may include dial-up telephone lines, broadband connection &

wireless devices.

i) Dialup connection:- #99

- ↳ Dial a no. & get confirmation from server
- uses the facilities of the public switched telephone net.
- Establish a connection to an ISP by dialing a telephone no. a conventional telephone line.
- PSTN (Public Switch Telephone network)
  - ↳ telephone lines, fibre optic, microwave transmission links, cellular net.
- Dial-up requires time to establish a telephone connection up to several sec. depending on the location
- Performs configuration protocol (synchronizer)
- Slower, can't used for media streaming.

ii) DSL (Digital Subscriber Line)

- Transmit digital data over telephone lines (Modem). DSL is a form of broadband comm<sup>n</sup> i.e. always "on", there is no need to dial a phone no. to connect.

iii) Broadband:- High speed internet access i.e. faster than traditional dialup access.

→ provided either cable or telephone companies.

iv) Cables : →

It is a form of broadband access. Cables modem can provide extremely fast access to the internet.

v) Satellite connection :-

This type of connection is provided specially in rural areas where broadband connection is not yet obtained (satellite dish) VISP

vi) Wireless connection : →

→ doesn't use telephone line or cables

to connect to the internet.

→ It uses radio frequency

→ It offers very high speed internet

eg :- wi-fi, bluetooth.

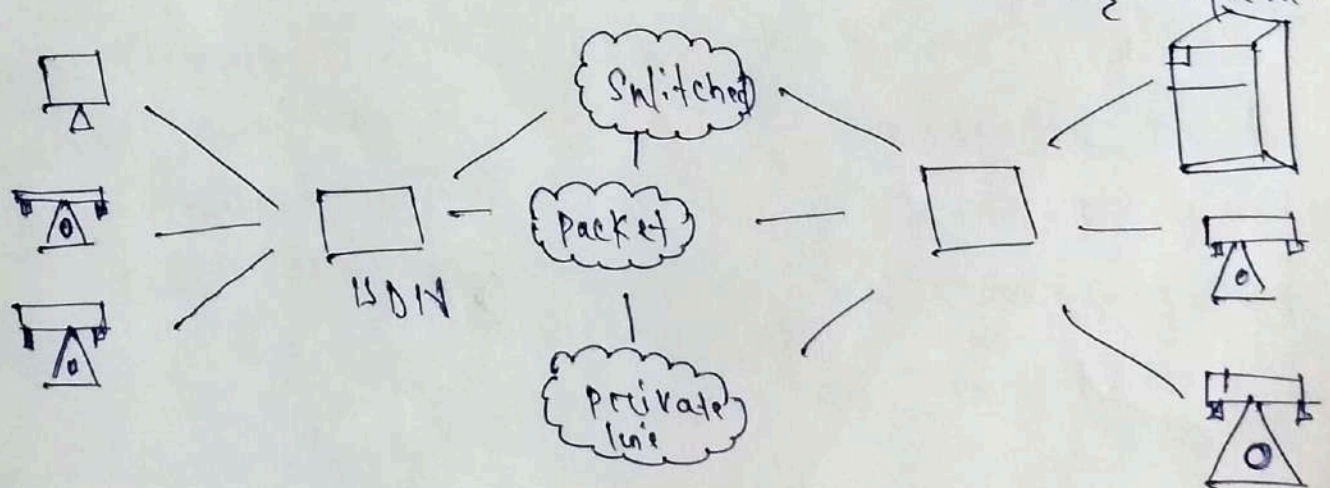

# ISDN (Integrated Service Digital Network)

→ The process of connecting a home computer to ISP used to take lot of effort (usage of modulator - demodulator / MODEM unit).

- The above fig. shows modem required to convert digital to analog & vice versa.
- What if the digital ~~into~~ signal into at one end reaches to the other end in the same mode, without all connection (modem)? It is this basic idea that lead to the development of ISDN.
- ISDN was first defined in the CCITT red book in 1998.
- ISDN is based on telephone n/w based infrastructure that ~~based~~ <sup>allows</sup> on transmission of voice & data simultaneously at the high speed.

## Services

- voice mail, Facsimile, video text, e-mail, image & graphics exchange etc.

## Types of ISDN

B-channel: → Transmit voice & data  
Bearer

D-channel → Signaling Purpose to  
Delta set up comm

## ISDN Service Interface:-

i) BRI (Basic Rate Interface)

2 B-channel & 1 D-channel

→ Small size enterprise

ii) PRI (Primary RI)

→ Requires high no. parallel calls

→ BRI helped in receiving & sending data from multiple users at a time

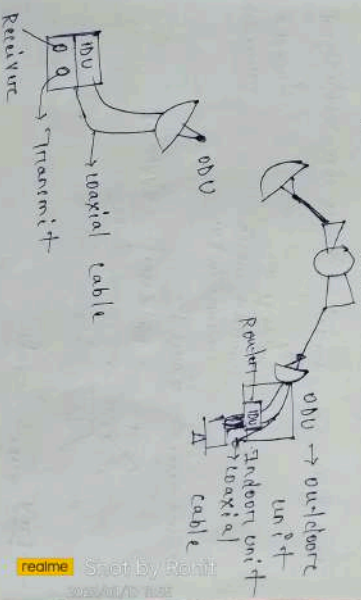

PRI

→ 23

### VSA T (Very Small Aperture Terminal)

VSAT is a two-way satellite ground station with a dish antenna which is used to transmit & receive data from satellite.

→ The data can be redirected to other remote terminal or hubs around the planet.

### Advant

↳ deployment of ground station communicate with satellite.

### Disadv

→ Signal quality affected by the weather & other building getting in the way.

RF Link :  $\Rightarrow$  Radio Frequency

$\Rightarrow$  Wireless Technology is rapidly evolving & playing an important role in our daily life throughout the world. (Mobile Phone, Smart Phone, Smart car / smart home etc)

$\Rightarrow$  How wireless signal transmit through air?

Antenna

(Transmission of signal)

Transfers Electrical signals to Radio signals

$\Rightarrow$  voltage or current which convey is EM

$\Rightarrow$  Transmit or receive data

Electromagnetic wave :  $\Rightarrow$

Radio signal  $\rightarrow$  Electrical

$\rightarrow$  Frequency unit : Hz

Frequency = no. of cycles per sec

Blue is color light and pink

Introduction to WWW (World Wide Web)

→ WWW is also known as web, is a collection of websites or webpages stored in webserver connected to local ~~server~~ computers through the internet.

→ These website contain text pages, digital images, audio, video etc.

OR  
→ It is an info. space where documents &

other web resources are identified by URLs, interlinked by hypertext links  
invented by Tim Berners-Lee

→ British computer  
Lee is the inventor of the web.

→ In simple term WWW is a way of exchanging info. bet<sup>n</sup> computers on the internet, trying them together into a vast collection of interactive multimedia resources.

\* Internet & web is not the same thing: web uses internet to pass over the info.

Web Architecture : →

→ WWW follows 2 tier architecture  
(webserver (produce & deliver info.)  
webclient (retrieve & display info))

## Internet

⇒ Internet is a massive net → way of accessing info. over the net, a networking the medium of the internet. infrastructure

→ It connects millions of computers forming a network which any computer can communicate with others. build on the top of internet.

→ Info. that travels over the internet does so via a variety of languages known as protocols.

→ It does not utilize web browser → utilize web browser

→ Provide structure → Dynamic net via a variety of methods & protocols

### App'l Level Protocol

There are several protocols which work for user in app'l layer.

→ It is broadly classified into 2 categories

i) Protocols which are used by users: For email.

ii) Protocol which help & support protocols used by users: DNS

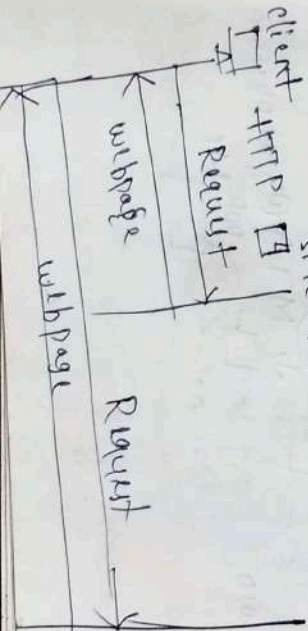

## 2) HTTP (Hypertext Transfer Protocol):

- ↳ Port no 80
- ↳ To Transfer or fetches the webpage on www (Access webpages to webserver)
- ↳ How to request + how to upload into webpage
- ↳ Itself not reliable but use TCP to achieve
- ↳ Inband protocol
- ↳ Send commands on data in same port)
- ↳ Stateless i.e. no info is stored who / how / when info is used
- ↳ 1/11 million of request

- ↳ cookies = Many companies
- ↳ HTTP 1.0 Non-persistent
- online banking (connection)
- ↳ HTTP 1.1 persistent (connection)
- ↳ commands (Head, Get, Post, Put, delete, connect) metadata

https ⇒ Secure Site A

→ Remotely file Transfer

→ port no. 20 (data) & 21 (control)

↳ connection

→ Not Inband

→ Both active at the same time

→ Data connection is non-persistent

→ control " " persistent

→ Reliable (No loss in bytes)

→ Synchronous

→ Stateful → Remote login

iii) SMTP & POP (Post office Protocol

↳ Simple Mail Transfer Protocol)

→ Backend of mail

→ Both Synchronous & asynchronous.

→ SMTP port: 25 (push the mail)

POP3 port: 110 (extract the mail)

• port 995 (secured)

15GB → mail account (space)  
25GB → to store the data

Mail client 

↳ fetch mail

google

@ gmail.com

(push)

Mail Transfer Agent

(push)

MTA@ yahoo.com

POP MC

⇒ MIME (Multipurpose Internet Mail Extension)

## Search Engine:-

SE is a s/w program designed to identify & respond to specific questions, called Keyword & populate the page called as SERP with relevant info. available on the web.  
(consisting lots of algo.)

↓  
Search Engine Result  
phase

↳ Key Factors / Stages

a) crawling ⇒ content is discovered

b) Indexing ⇒ content is analyzed & stored in a db

c) Search Results (Retrieval) → user query fetched & displayed

### Types

i) crawler based ⇒ google, yahoo, bing, Baidu!

ii) Hybrid search engine ⇒ googlenews

iii) Human powered directories ⇒ open directory system

iv) other special search engine

↳ site owners (short description of the site)

↳ Keywords (Searchbox will match with description of site)

## Proxy Server:-

Retrieves data on the internet on behalf of a user.

29  
webpage

http://www.example.com

Proxy benefits :-

↳ privacy = allows you to surf the internet anonymously.

(hide IP address)

11.22.33.44

(public IP address)

\* Without using a proxy, our public IP address is visible.

Proxy server IP address is shown

↳ speed proxy server store cache webpage

↳ saves bandwidth

↳ Activity logging (keep records)

↳ block

⇒ A proxy server cannot encrypt data

⇓ VPN (virtual private N/W)

(private + encrypt)

How to make proxy server

↳ go to browser

↳ find proxy list

↳ open site

↳ free proxy button

↳ list

↳ proxy time (S/W)

(free)

↳ proxy server (config)

↳ add

address

& port

↳ paste IP address =

↳ enables https

↳ OK

CGI

# important Method of parameter passing

## 1. pass BY value

~~changes made to~~  
copy of actual parameter's value is made in memory. i.e. the caller & callee have two independent variable with same value.  
→ If the callee modifies the parameter value, the effect is not visible to the caller.

eg :  $\Rightarrow$  void abc(<sup>10, 20</sup>val1, val2)

```
ge. void abc(num1, num2)
{
    x = 40;
    y = 50;
}
```

class callbyvalue

```
{
    public static void exp(int x, int y)
    {
        x++;
        y++;
    }
}
```

```
}
public class main {
```

```
    public static void main(String args[])
```

```
    {
        int a = 10;
        int b = 20;
```

```
        callbyvalue ob = new callbyvalue();
```

```
        ob.exp(a, b);
```

```
        System.out.println(a, b);
```

```
    }
}
```

When?

If we are building multi-thread appl<sup>n</sup>, then we don't have to worry objects getting modified by other thread.

→ J+ keeps object sync.

call by Reference (aliasing):—

↳ Pass the address of an argument in the calling fun<sup>n</sup> to the corresponding formal parameter of the called fun<sup>n</sup>, so that copy of the address of the actual memory

→ caller & callee use same variable  
(callee modifies visible to caller)

eg class callbyR

```
{ int a, b;
```

```
  callbR (int x, int y)
```

```
  { a = x;  
    b = y;
```

```
  }  
void change value (callbyR obj)
```

```
{ obj.a += 10;
```

```
  obj.b += 20;
```

```
  }  
}
```

```
public class main
```

```
{ psumc ... }
```

```
  callby R ob = new R (10, 20);
```

## common Gateway Interface (CGI):-

→ The CGI is a standard way for a web server to pass a web user's request to an appl<sup>n</sup> program & to receive data back to send to the user.

→ When a user requests a web page, the server sends back the requested page. However, when a

→ Whenever a user fills out a form on a webpage & sends it in, it usually needs to be processed by an appl<sup>n</sup> program.

(The web server typically passes the form info. to a small appl<sup>n</sup> program that process the data & may send back a confirmation msg).

\* → This method or convention for passing data back & forth between the server & appl<sup>n</sup> is called CGI.

< Form method = post action = = >

## URI (Uniform Resource Identifier)

URI  $\Rightarrow$  URL  $\xrightarrow{\text{(location)}}$  URN  $\Rightarrow$  (name of the URL)

URL  $\rightarrow$  address of the resource on the  
↳ location internet.

→ URI is a sequence of characters that identifies a web resource by location name

on both available on the internet.

→ URL is the sequence of characters that only identifies the location of a resource available on the internet.

website & Services  
bibliographies  
to look up author & their

## Advantages

- i) Essential to the semantic web becoz it prevent ambiguity.
- ii) Search the name as well as the location, which is in info. format.

## Dreamweaver

- ⇒ It is a s/w program for designing web pages, essentially a more fully featured HTML web & programming editor.
- ⇒ it provides WYSIWYG (What you see is what you get) interface to create & edit web pages.
- It support many markup lang. XML, HTML, CSS, Javascript. (It also support human language)
- It was originally developed and published by Macromedia in 1997. Later Adobe purchased macromedia in 2005 & continued the development of the program.
- It is the Licensed based (with subscription)

## Introduction to Security

### Security

When we create a system that store & retrieve data, it is important to protect the data from unauthorized use, disclosure, modification & or destruction.

⇒ When a system has no security, then it is open to malicious or unauthorised access.

Goals  
⇒ CIA belongs to an info security

model which is consist of 3 things

a) Confidentiality : ⇒

→ It means data is only available to authorized parties. When info. has been kept confidential it means that it has not been compromised by other parties.

→ Confidential data are not disclosed to people who should not have access to them.

b) Integrity : ⇒

Data is not tampered with or degraded during or after submission.

→ The data has not been subject to unauthorized modification, either intentional or unintentional.

c) Availability :- →

Info. is available to authorized users when it is needed.

## Types of Security :- ⇒

### Authentication & Authorization

Authentication :- It is about validating your credentials like username & password to verify your identity.

eg :- Entry ticket

Authorization :- It is the process to determine whether the authenticated user has access to the particular resource.

→ It checks your rights to grant you access to resources such as info, db, files etc.

# Authentication

vs

# Authorization

→ Verification

→ <sup>who</sup> permission

→ Who

→ What

→ When

## Firewall :->

It is a system that is designed to prevent unauthorized access from entering a private net.

→ creates a safety barrier bet<sup>n</sup> a private net & the public net internet  
→ Large org

## Firewall Rules

### Permission

IP address

Protocol

Destination Port

\*

=

any

# Open Research & Contribution

## Types of Security:-

Security refers to protection of devices, process & infrastructure & assets of an org<sup>n</sup> from attacks, data threats, unauthorized access etc.

### Types

#### 1) Appl<sup>y</sup> Security

It measures the ~~extent~~ <sup>extent</sup> vulnerability, attacks that arises in the development stages of appl<sup>y</sup> such as development, deployment & maintenance & upgrade

= <sup>Automated</sup> Parameter

Validation

Session

User

Management

Authentication

→ Appl<sup>y</sup> Security is the process of developing, adding, & testing security features within appl<sup>y</sup> to prevent <sup>being exposed</sup> security vulnerability against threats such as unauthorized access & modification.

ii) Parameter Validation: → Automated processing in a module to validate the spelling or accuracy of parameters passed to that modules.

iii) Session Mgt. → process of security handling multiple requests to web-based appl<sup>y</sup> or service from single user.

## b) Info. Security

Protection info. & data from <sup>theft,</sup> threat, access denied, Breaches etc. to prevent to provide privacy.

## c) Disaster Recovery

involve planning & strategy to set of policies & procedures to enable the recovery or continuation of vital technology.

Risk Assessment      Risk Analysis      priority

## d) Network Security

Monitoring & preventing of ~~unauthorised~~ access & exploitation of internal n/w.

→ Access denied

IPS, VPN, Firewall

## e) Website Security

— website scanning & malware removal

→ website app' firewall,

→ App' security testing

## f) Endpoint Security

~~Security~~ Security end point on entry points

on end users device such as desktop laptops

& mobile from being exploited by malicious

actors

# Antivirus

Firewall (Network)  $\Rightarrow$  Separate incoming n/w data is secure or not.

$\Rightarrow$  It is a system designed to prevent unauthorized access from entering a private

(to & from internal n/w)

$\rightarrow$  It is a n/w security device that monitors incoming & outgoing network traffic & decides whether to allow or block specific traffic based on a defined set of security rule.

$\Rightarrow$  Acts like a barrier.

$\Rightarrow$  Host based and N/w based Firewall.

$\Rightarrow$  Software based  $\Rightarrow$  can whole n/w  
dedicated hardware based  
 (Server)

## Types of Firewall

i) Packet filtering Firewall (Layer-4)

P, D, N, T

$\Rightarrow$

→ Set of rules

11)

Source Address, Destination address, Port

no., Protocol.

→ If rule matched then forwarded or discard

→ Default action.

if no. rules is defined / matched

then it automatically discard.

→ Data / Payload

4GT only check, Sa, da, & Port & no. Protocol

but data can't be checked so it is less

Secure (data may be malicious).

ii) App<sup>n</sup> Level Gateway:-

(proxy server)

→ More Secure

→ processing overhead

→ check data / payload

## SSL (Security Socket Layer)

→ If two entities try to communicate with each other / transfer data among them they want security which is done by SSL.

→ Security bet<sup>n</sup> of transferring data bet<sup>n</sup> client & server.

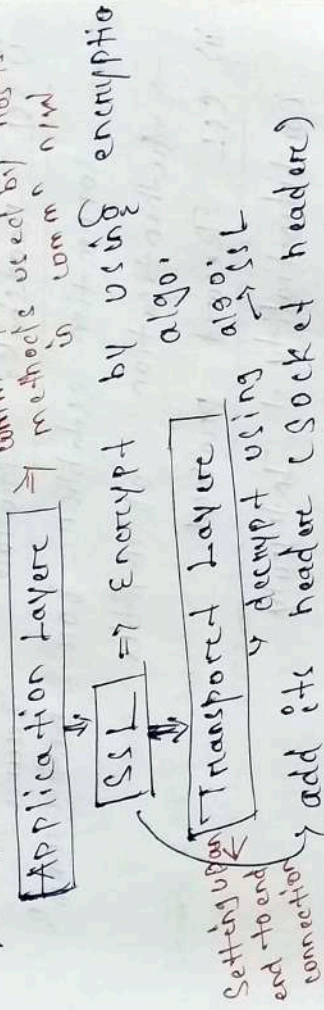

Goals

- i) Integrity

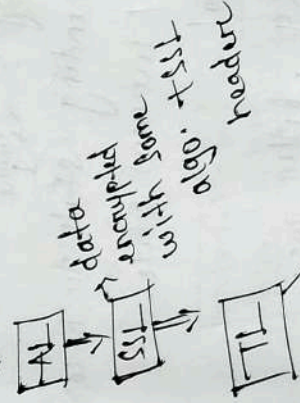

- ii) Authentication

- iii) Confidentiality

Position of SSL

Sender

Receiver

* SSL Handshake Protocol	SSL Change cipher spec Prot.	SSL Alert Protocol	HTTP
* SSL Record Protocol			
TCP			
IP			

### SSL Protocol Stack

i) SSL Handshake Protocol Secure ~~better~~ comm<sup>n</sup>.

- connection establish for
- Authentication of entities

ii) SSL Record Protocol

Confidentiality + Integrity

iii) SSL Change cipher spec Protocol

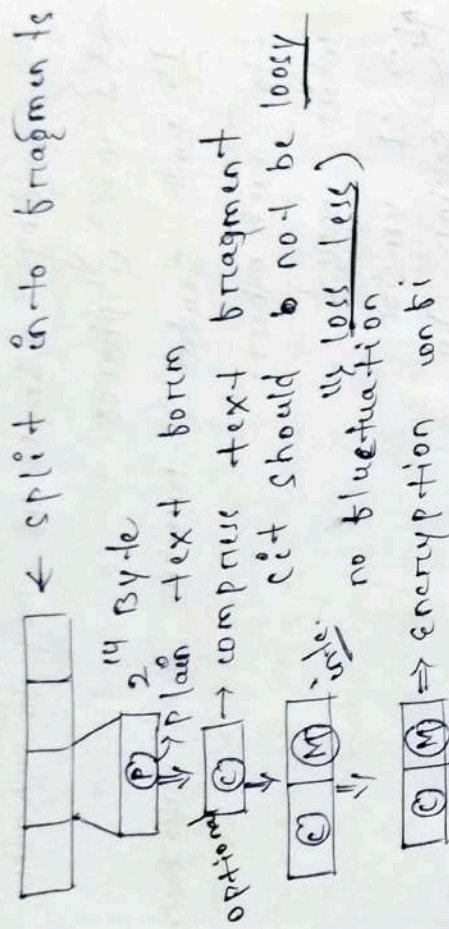

consist of 1 single msg (1 byte)   
 value 1

→ It simply causing the pending state to be copied into the Running state / current state

iv) SSL Alert Protocol

→ Alert msg, warning msg, fatal msg

a) SSL Record Protocol  
 ⇒ confidentiality + Integrity  
 (Msg Authentication code)  
 encryption algo.)

M-AC MSG Authentication code): -

we use Secret key to generate a small fixed size of data. called M-AC.

$$M-AC = C(K, M) \xrightarrow{\text{key common key}} \text{mac bundle msg}$$

↳ Short piece of info. used to authenticate a msg.

content type	Major version	minor version	compression length
<div> <div>                     pointer to compressed data                 </div> <div>                     MAC                 </div> </div>			
Encrypted			

## b) Handshake Protocol

It is used to establish sessions. This allows the client & server to authenticate each other by sending a series of msg to each other.

It uses 4 phases

1) Both sender & receiver send hello packets to each other.

which consist

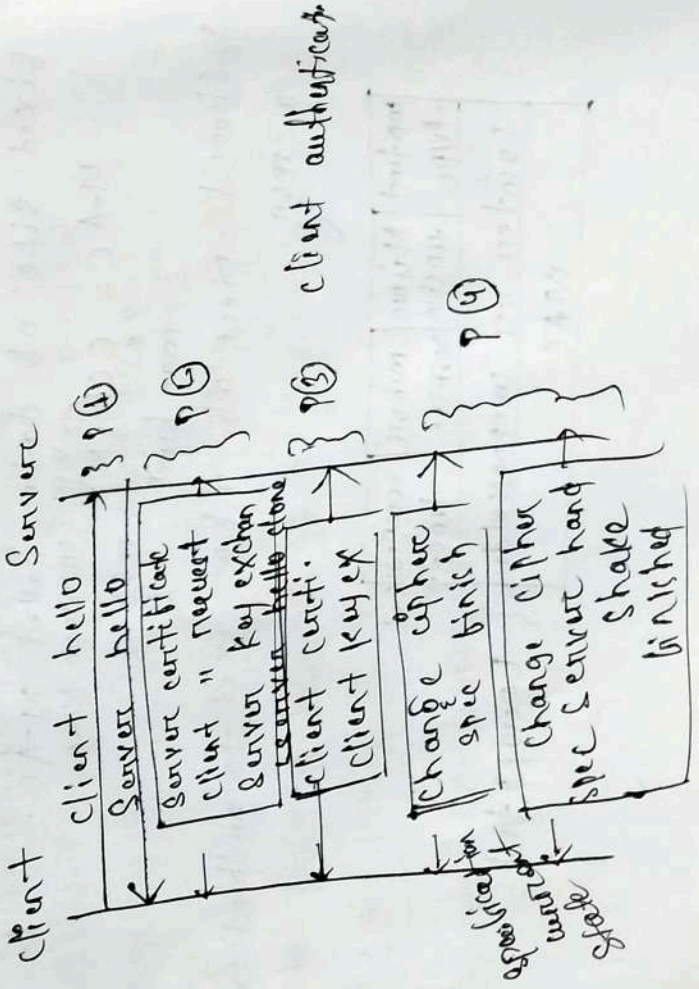

→ SSL version

→ Session ID

→ cipher suite (list of cryptographic algo supported by client)

→ compression method (encryption algo.)

2)

c) Alert protocol

Level - Alert

contains specific information  
 indicate alert

→ types of alert

Warning Fatal

Alert has by C Break connection, but no impact on the connection bet sender & receiver

- Types of alert
- close - notify ⇒ No more msg sender
  - unexpected msg ⇒ Incorrect msg received
  - Bad - word - mac ⇒ wrong mac received
  - Bad - certificate ⇒ Received corrupted certificate
  - certificate expired

E-mail & E-mail protocol (ex)

Internet Access MSG protocol

↳ used bet<sup>n</sup> client

SMTP → used bet<sup>n</sup> servers

↳ return receipt functionality

msg not in server (poll protocol)

google storage.

# Telnet

## Teletype Network

→ 1969, Officially March 1973

→ Network Protocol which virtually connect the computers (Remote login)

eg Teamviewer, anydesk ⇒ cable internet

Remote Access use telnet ⇒ not use currently ⇒ e-commerce

proper command

userid =  
passwd =

No security guard  
(Not encrypted)

SSH (Security shell) Protocol start

google passwd

start Remote disk top

remote desktop setting  
⇒ enable

Telnet cmd : ⇒

connection ⇒ additional operation

name computer name (right click)

#1

install telnet package

# telnet

New Groups ⇒ chat room / club

## Video conferencing $\Rightarrow$ components

- 1) The Hardware
- 2) The intervening NW that carries the signals bet<sup>n</sup> sites
- 3) The conference environment or room

### a) Hardware

- $\rightarrow$  Camera
- $\rightarrow$  Microphone
- $\rightarrow$  video conference unit:  $\Rightarrow$  encoder / decoder accepts vision & sound signal & processes them into suitable format.
- $\rightarrow$  Display unit: - Projector / TV,
- $\rightarrow$  Audio system  $\rightarrow$  good audio system, speakers.

### b) Network

- $\rightarrow$  IP, ISDN

### c) Environment

- $\rightarrow$  lighting is an easy to improve picture quality.

### Benefits

- $\rightarrow$  Sharing Presentation
- $\rightarrow$  2 way comm<sup>n</sup>
- $\rightarrow$  Greater access<sup>to</sup> experts / specialists
- $\rightarrow$  Productive use of time (reduce travel time)

### disad

- $\rightarrow$  Lacking of self discipline / Lazyness
- $\rightarrow$  <sup>lack of</sup> Interpersonal relationship
- $\rightarrow$  image ~~more~~ movement is jerky

E-commerce → electronic media / gadget

→ Electronic Marketing

→ Buying & Selling goods & services over an electronic system such as internet.

→ E-commerce is purchasing, selling & exchanging goods & services over computer N/W or internet through which transactions or terms of sale are performed electronically.

Flipcart, Amazon

E-commerce

E-business

→ customers

→ customers + employee + supplier

→ Exchange

→

Process

→ Consumer uses web browser to connect to the home page of a merchant's website on the internet  
→ (Google Chrome) → (website's URL)

→ Consumer browses the catalog of products <sup>displayed</sup> on the site & selects items to purchase. The selected items are placed in the electronic equivalent of a shopping cart.

→ When the consumer is ready to complete the purchase of selected items, she/he provides a bill-to and ship-to address for purchase & delivery.

## Types : →

i) B2B (e-commerce bet<sup>n</sup> companies)

eg Intel selling microprocessor to Dell  
Heinz selling ketchup to Mc Donalds  
wholesaler

ii) B2C (bet<sup>n</sup> companies & consumers)

eg: - Amazon

Dell selling me to a laptop

iii) B2G (companies & public sector)

eg Be pay taxes, file report.

iv) C2C (private individuals or consumers)

eg = OLX, second hand product.

v) G2C (e-governance)

→ Services provided to users/consumers through website. etc.

## Web Site : →

→ A website is a collection of webpages.

→ To access website, we need web browser.

→ Every website has an URL is an address using which we can access website on web server.

## Types

Static website

DV

→ content & layout is fixed.

→ No db & no user interaction

→ No server side appl<sup>n</sup> program

→ Easy to create & low price

→ Direct comm<sup>n</sup> bet<sup>n</sup> webserver & user.

→ Require only html & same  
eg: → tutorial point (content)

### Dynamic website

→ content & layout is not fixed (diff. for diff. users).

→ Presence of db

→ HTML Page depends on user's input.

→ costly & difficult to create.

→ Need a lot of knowledge<sup>of PL</sup>, db skills.

eg: Amazon (cart)

### Webportal customized website

→ website having login details for accessing content. → (daily update)

→ Used for Private content

eg: → google, yahoo, youtube etc

govt. Portal, educational Portal

### Public Job Portal

Vertical ⇒ only one topic

eg business

horizontal ⇒ diff. topic

Knowledge ⇒ info. provide

Enterprise → org<sup>n</sup> related / Employee's service

Market place Portal → Amazon

### Social Networking Sites : →

Helps us to connect with people from all over the world.

→ we can communicate with our near & dear ones anytime & anywhere. grow business &

→ It helps the people to establish & maintain relationship with people from all over the world through social networking.

→ Many social networking sites like Facebook, Instagram, Twitter, WhatsApp etc managed to bring the world closer & helped many people to connect & expand their business globally.

→ Social networking can be classified into blogging, broadcasting, online community etc

RSS Feed (Real Simple Syndication)

→ Move content to others.

→ Keep track of things in real time

→ Feed readers are programs which display RSS feeds websites that you subscribe.

→ Help you to stay up-to-date with your fav. newscast, blogs.. etc. instead of visiting sites to find new posts, or

→ Way for website authors to publish notifications of new content on their website.

## How! RSS

- 1) open a web browser & go to a web page
- 2) Right click on the web page & choose View Page Source.
- 3) Select Setting & bind
- 4) TYPE RSS & Press enter.
- 5) The instance of RSS are highlighted in the Page Source.
- 6) Right click the RSS feed url & Select copy link address.
- 7) Use this url to subscribe to the RSS feed in an RSS reader.

HTML: Defines the content of web pages

CSS: Specify the layout of web pages

Javascript: program the behaviour of web pages

PL  $\Rightarrow$  Set of code / to tell computers what to do & how to do.

(through SW) java, C, C++ etc

SL  $\Rightarrow$  connect 1 language to another  
Php & html (no standalone)

$\rightarrow$  instruction \* (No compilation)

Markup lang  $\Rightarrow$  look, structure  $\rightarrow$  quick (used in website)

CSS + HTML

Types of Scripting Language  $\Rightarrow$

a) Server-side scripting

run on a web server, when a client sends a request, the server responds by sending content via http.  $\rightarrow$  They are not viewable by the public like

b) client-side scripting

run on the client end - on their web browser.

benefits  $\rightarrow$  They can reduce demand on the server side script, allowing web pages to load faster.

eg  $\Rightarrow$  client-side script focused on faster processing, UI, & functionality.

$\rightarrow$  Server-side focuses on faster processing, access to data, resolving errors etc

## Java Script

→ The client is the computer system including tablets, & mobile devices) which is running the web browser. <sup>→ controlling</sup>

→ client side scripting can be used to make web pages changes after they arrive at the web browser.

→ client side scripts can also be used to perform validation of data entered into forms, either using JavaScript or some new features of HTML5.

→ JavaScript is the main client side

Scripting language that can be used to create, delete, & manipulate HTML document.

\* JavaScript is a dynamic PL (allows you to implement ~~an~~ dynamic feature on web) <sup>→ object oriented</sup>

→ JavaScript embedded into a HTML document program with the help of `<script>` tag

→ It is a paired tag. Embedded with in the `<head>` or `<body>` tag of the HTML

Syntax: `<script language = "JavaScript">`  
== `<script>`

29 php, Asp.net, node.js, Java, Ruby, Perl,  
Server side      web app      window  
Python      appl'n      linux  
(client side)

HTML, CSS, Javascript  
(client side)

Pros :  $\Rightarrow$

- i) No requirements to compile,
- ii) Scripting lang. make webpages look awesome.
- iii) Easier to learn & write.
- iv) Scripting can be used as a Prototype for Programs, saving time on test & project.
- v) ~~Plat~~ performance.

Declaring variables :  $\Rightarrow$

$\Rightarrow$  Variables are containers for storing data

Syntax var variablename = value;

eg var a = 5;

Rules :  $\Rightarrow$

- i) Name starts with a letter (a to z) or A to Z, underscore (-), or dollar sign.
- ii) After first letter we can use digits  
Valid      123 X

3) Javascript variables are case sensitive

eg x & X

<script>

var x = 10;

var y = 20;

var z = x + y;

document.write(z);

</script>

### Built-in Function

Fun<sup>n</sup> :  $\Rightarrow$  Reusable block that will be executed whenever it is called.

$\rightarrow$  great time saver

$\rightarrow$  provides no. of built in fun<sup>n</sup>

fun<sup>n</sup>()  
{  $\equiv$  code }

Fun<sup>n</sup>

Description

is Nan()

$\rightarrow$  Not a no.

Return true if the object is not a no.

parseFloat(string)

String(object)

eval

User-Defined fun<sup>n</sup> :  $\Rightarrow$

$\Rightarrow$  It is written in bet<sup>n</sup> the <head> section of the html block & call on a particular body

Syntax :  $\Rightarrow$  Function add()

{

var a, b;

var sum = 0;

document.write("Addition : + "sum);

}

eg :

<html>

<head>

Language = JavaScript

<script type=

Function add()

{ var a = 10, b = 20;

var c = a + b;

document.write(c);

}

</script> </head>

<body>

<input type = "button" onclick = "add()" value = "Click" >

</body> </html>

Array in Javascript :  $\Rightarrow$

Arrays are Javascript object that are capable of storing a sequence of values.

$\rightarrow$  These values are stored in index location with con

Syntax :  $\Rightarrow$

```
var arr = [10, 20, 30, 40];  
document.write(arr[0]);
```

class A

@@

at 0:10

```
arr[0]; A ob = new A();
```

Dense array :  $\Rightarrow$  with specific value of array

Creating objects in Javascript :-

```
var a = { }; // object literals
```

```
a['Rahul'] = 200;
```

a[Rahul] = 200

b) Object Literal Declare & Initial

abc = ?

```
var a = { Rahul : 200 };
```

c) object constructor

```
var a = new object();
```

d) Factory fun<sup>n</sup>

~~ex~~ ~~function~~ ~~act~~

function

```
{
```

```
return
```

```
{ Rahul : 200;
```

```
} }
```

e) constructor Function

```
function A()
```

```
{
```

```
this.Rahul = 200;
```

```
this.Sonam = 300;
```

```
}
```

## ① Conditional Statement in JS

- Very often when we write code, we want to perform different actions based on different decisions. For that scenario we use conditional statement.
- In JS we have the following conditional statement
- a) use if to specify a block of code to be executed, if a specified condition is true.
  - b) use else to specify a block of code to be executed, if the same condition is false.
  - c) use else if to specify a new condition to test, if the 1st condition is false.
  - d) use switch to specify many alternative blocks of code to be executed.

a) The if Statement:

Executed if a condition is true

Syntax: if (condition)  
{  
    code to be executed if cond<sup>n</sup> is true;  
}

eg :- if (5 > 3)  
{  
    greetings = "Hello";  
}

<script>

var a = 10;

if (a > 5)

{

    document.write("Hello");

</script>

b) The if else statement

- It evaluates the content whether cond<sup>n</sup> is true or false  
→ The else statement to specify block of code to be executed if the condition is false.

Syntax if (condition)  
{  
    if the cond<sup>n</sup> is true;  
}  
else  
{  
    condition is false;  
}

```
<script>
var a = 20;
if (a % 2 == 0)
{
    document.write("a is an even number");
}
else
{
    document.write("a is odd number");
}
</script>
```

c) The else if statement:

use the else if statement to specify a new condition if the first condition is false

Syntax if (cond<sup>n</sup> 1)  
{  
    condition 1 is true;  
}

else if (condition 2)

```
{  
    condition 2 is true;
```

```
}
```

```
else
```

```
{
```

```
    condA 2 is false;
```

```
}
```

eg <script>

```
var a = 20;
```

```
if (a == 10)
```

```
{
```

```
    document.write("a is equal to 10");
```

```
}
```

```
else if (a == 20)
```

```
{
```

```
    document.write("a is equal to 20");
```

```
}
```

```
else
```

```
{
```

```
    document.write("None of the above");
```

```
}
```

4) The Switch Statement

It is used to perform different actions based on different conditions

Syntax: Switch (expression)

```
{
```

```
    case x:
```

```
        // code
```

```
        break;
```

```
    case y:
```

```
        // code
```

```
        break;
```

```
    default:
```

```
        // code
```

```
}
```

- The Switch expression is evaluated once
- The value of the expression is compared with the value of each case.
- If there is a match, the associated block of code is executed.
- If there is no match the default code block is executed.

eg: <script>

```
Var number = 10;
```

```
Switch (number)
```

```
{
```

```
  case 10:
```

```
    document.write("The value is 10");
```

```
    break;
```

```
  case 20:
```

```
    document.write("The value is 20");
```

```
    break;
```

```
  default:
```

```
    document.write("None");
```

```
}
```

## Loops in JS :-

Javascript loops are used to iterate the piece of code using for, while, do while loop.

### Types of Loop

1. For Loop

2. do while Loop

3. while loop

5)

## 1) For Loop:

The JS for loop iterates the elements over the fixed number of times.

→ It should be used if number of iteration is known.

### Syntax

for(initialization; condition; increment)

```
{  
  code to be executed  
}
```

eg <script>

```
for(i = 1; i <= 5; i++)
```

```
{  
  document.write(i + "<br/>")  
}
```

</script>

## 2) JS while Loop

The JS while loop iterates the elements over the infinite no. of times.

→ It should be used if no. of iteration is not known.

### Syntax

while(condition)

```
{  
  code to be executed  
}
```

eg <script>

```
var i = 11;
```

```
while(i <= 15)
```

```
{
```

```
document.write (i + "<br />");  
i++;  
}
```

</script>

3) JS do while Loop

The JS do while loop iterates the elements

both the infinite no. of times like while loop.

→ But, code is executed at least once whether cond<sup>n</sup> is true or false

Syntax      do  
                 {  
                 code to be executed  
                 } while (cond<sup>n</sup>);

<script>

var i = 21;

do

{ document.write (i + "<br />");

i++;

} while (i <= 25);

</script>

Document Object Model (DOM):

#### ④ JavaScript Array;

It is an object that represents a collection of similar type of elements.

→ There are 3 ways to construct array in JS

1. By Array literals
2. By creating new instance of array directly (using new keyword)
3. By using an array constructor (using new keyword)

##### 1) JS Array Literals

The syntax of creating array using array literal is given below -

```
var arrayname = [value1, value2 ... valueN];
```

eg <script>

```
var name = ["Ram", "Hari", "Sita"];
```

```
for (i = 0; i < name.length; i++)
```

```
{
```

```
    document.write (name[i] + "<br/>");
```

```
}
```

```
</script>
```

##### 2) JS Array directly (new keyword)

```
var arrayname = new Array();
```

↳ create instance of array

```
<script>
```

```
var i;
```

```
var name = new Array();
```

```
name[0] = "Ram"
```

```
name[1] = "Hari"
```

```
name[2] = "Sita"
```

```
for (i = 0; i < name.length; i++)
```

```
{  
    document.write(name[i] + "<br/>");
```

```
}
```

```
</script>
```

3) JS Array constructor (new keyword)  
You need to create instance of array by passing arguments in constructor so that we don't have to provide value explicitly.

```
<script>
```

```
var name = new Array("Ram", "Hari", "Sita");
```

```
for (i = 0; i < name.length; i++)
```

```
{  
    document.write(name[i] + "<br/>");
```

```
}
```

```
</script>
```

## JavaScript objects

JS object is an entity having state & behaviour (properties & method)

eg car, pen, bike, chair, glass etc

→ JS is an object based language. Everything is an object in JS

③ → we don't create class to get the object. But, we directly create objects.

There are 3 ways to create objects

1. By object Literals
2. By creating instance of object directly (using new keyword)
3. By using object constructor (using new keyword)

#### 1. JS object by object Literals

The syntax of creating object using object literal is given below:

```
object = { property: val1, property2: val2, ... }
```

```
<Script>
```

```
emp = { id: 102, name: "Monali", Branch: "CSE" };  
document.write(emp.id + " " + emp.name + " " +  
Branch);
```

```
</Script>
```

#### 2) By creating instance of object:

The syntax of creating object directly is given below:

```
var objectname = new object();
```

```
<Script>
```

```
var emp = new object();
```

```
emp.id = 101;
```

```
emp.name = "Monali";
```

```
emp.Branch = "CSE";
```

```
document.write(emp.id + " " + emp.name + " " + emp.Branch);
```

```
</Script>
```

5) By using object constructor  
Here, we need to create function with arguments.

- Each argument value can be assigned in the current object by using this keyword
- The this keyword refers to the current object

eg <script>

```
function emp(id, name, branch)
```

```
{  
  this.id = id;  
  this.name = name;  
  this.branch = branch;  
}
```

```
e = new emp(105, "Monali", "CSE");
```

```
document.write(e.id + " " + e.name + " " + e.branch);
```

```
</script>
```

DT - 03.01.22

## Event Handling in JS

↳ The change in the state of an object

Events : Events are the actions that can be

detected by Javascript

eg. When a user click the mouse

• When a web page has loaded

• Image has been loaded

• Mouse moves over an element.

• Input field changed

• HTML form is submitted

• User strokes a key

→ Sometimes we want to execute a JS when an event occurs, such as when a user clicks a button.

→ Event ⇒ +fun

### \* Binding

→ What Event you want to perform?

→ Which HTML Element?

→ JS function.

→ event attribute

<P

onmouseover = "function()"

≡ <P>

Event attributes :

• onload : → A page is finished loading

• onunload : → The user exits the page

• onblur : → An element loses focus

• onchange : → The content of a field changes

• onclick : → Mouse clicks on object

• ondblclick : → Mouse double click on object

- onfocus → get text is selected
- onkeydown → A keyboard is pressed
- onkeypress → A key is pressed or held down
- onkeyup → The keyboard key is released
- onmousedown → mouse is pressed
- onmousemove → mouse is moved
- onmouseout → The mouse is moved off an element
- onmouseover → The mouse is moved over an element
- onmouseup → mouse button is released

```

<html>
  <head>
    <body>
      <h1> Welcome to my page </h1>
    </body>
  </html>

```

```

<html>
  <head>
    <script>
      function effect()

```

var x = document.getElementById("para1");

```

    x.style.backgroundColor = "lightblue";
  </script>
</body>
<h1> Welcome </h1>
<div id="para1" onmouseover="effect()">
  This is my 1st page </div>
</body>
</html>

```

## document object

open(), close(), write(), getElementById()  
write(), writeln()  
objectName.parentNode

cookie

domain

location modified

document mode

readyState

referrer

title

url

## clickEvent:-

<html>

<head> JavaScript Events </head>

<body>

<script language="JavaScript" type="text/JavaScript">

function clickEvent()

{ document.write("This is JavaScript");

} // ->

</script> </body>

<input type="button" onclick="clickEvent()"

value="who" this">

</body>

</html>

Embedding Javascript with HTML  
You can embed the Javascript code directly  
within your webpages by placing it bet<sup>n</sup>  
the `<script>` & `</script>`

& indicates the browser that the  
contained statements are to be interpreted  
as executable script & not HTML.

Ex :-

```
create  
<script type = "text/javascript">  
≡ code
```

```
</script>
```

```
<html>
```

```
<head> <script>
```

```
document.write ("Hello");
```

```
document.write (" <br /> ");
```

```
var msg = "R u fine";
```

```
document.write (msg);
```

```
</script>
```

```
<body>
```

```
<script>
```

```
var a = 10;
```

```
var b = 20;
```

```
var c = a + b;
```

```
document.write ("Result : " + c);
```

```
</script>
```

```
</body> </html>
```

if calling an External Javascript file :-

• is file

→ You can also place on javascript code into a separate file with .js & call that file in ur document through the src attribute

```
<script src = "js/hello.js"></script>
```

a.js

eg: var str = "Hello"  
document.write(str);

<html>

<head> </head>

<script src = "a.js"></script>

<body> </body> </html>

bold :- as a string

document.write ("<b>" + " </b>");  
"style = 'color: red'"

Cookie ⇒ Small files, (username, pwd), often including unique identifiers that web servers send to browsers (stored in cache)

→ These cookies than can be sent back to the server each time your browser request a new page.

→ It's a way of website to remember you, your preferences & your habits online

→ When u visit a website that uses cookies, a file is saved to Your PC, Mail, Phone or tablet

if u go back to that website again, the website knows You've already been there before.

How to create cookies :> 3rd party cookies dangerous

Syntax :>

i) document.cookie = "name = value";

ii) document.cookie = "name = value"; expires = date; domain = domain;

path = path; secure;

iii)

max-age = in second

create all browser support

eg :>

i) document.cookie = "username = 'geeky'"  
= Email id created

ii) document.cookie = "username = ..."; expires = Mon

; 3-Sep-2022 09:00:00 UTC;

iii)

max-age = "3600" + 60\*60\*24\*7  
14 days

Note

Name-value pair must not contain any

whitespace characters, commas, or semicolons

Morali Patel ✗

ii) optional cookie Attribute  
 Max-age, expires, domain, path, secure  
 (Fill automatically with reasonable defaults)

Step :->

open chrome  
 by settings

\* block 3rd party cookies  
 \* Ask permission

by Advanced  
 by Privacy & Security  
 by content settings  
 cookies  
 by - Allows

See all data

<html>  
 <head><title> cookie </title> </head>

<body> <h1> cookies </h1>

<script>

document.cookie = "username = mgha";  
 alert(document.cookie);  
 </script> </body> </html>

connecting database using Javascript in HTML

Page :->

<html>

<head> <title> Database </title> </head>

<body>

<body>

Full = "script" <script> </script> </body>

type

option

<table>  
<tr>  
<td> <form> <div>  
<label> Full Name </label>  
<input type =

~~creating a form using JavaScript in HTML~~

Server Side Scripting:-

→ It is basically used to create dynamic pages.  
(Web Servers are used to execute SSS)

→ CSS

→ Source code is visible to users.

→ Depends on browser & version

→ It runs on user's computer

→ doesn't provide security

→ HTML, CSS, JS

SSS

→ Source code is not visible to users

(o/p of Server side is a HTML page)

→ Any server side technology is used

→ It runs on web server

→ Security for data.

→ PHP, Python, Java, Ruby etc are used

M  
[ ]

\* array :  $\rightarrow$  contiguous memory location with same type of data

`a[4]`

`int a[5];`

$\rightarrow$  both memory allocated

JS

`a = new`

`a[5];`

size

`a[5];`

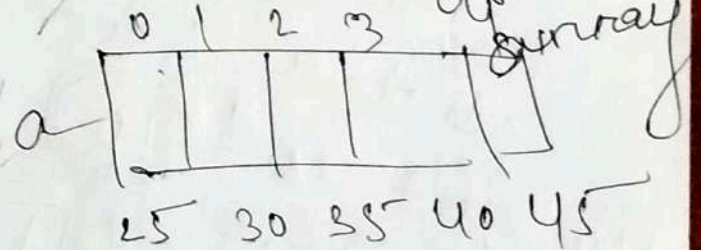

`a[0] = 25;`

`a[1] = 30;`

`a[2] = 35;`

`a[3] = 40;`

`a[4] = 45;`

`int a = 10;`

`int b = 20;`

if-else

`if (a > b)`

`{ print("a is greater");`

`}`

`else`

`{ print("b is greater");`

```

var day = Sunday;
if (day == Sunday)
{
    document.write("It's weekend")
}
else
{
    document.write("It's working day")
}

```

Unary on

++a / a++

int a = 10;

++a = 11

~~a++~~  
10    11

### Syntax to write PHP :-

The PHP parsing engine need a way to differentiate PHP code from other element in page, this mechanism is called Escaping to PHP

→ There are 4 ways to write PHP

- i) Canonical PHP tag : `<?php ?>`
- ii) Short-open php tag : `<?...?>`
- iii) ASP-style tag : `<%...%>`
- iv) HTML script tag

```
<script language = "php" > ... </script>
```

code <!DOCTYPE html> abc.php

```
<html>
```

```
<body>
```

```
<?php
```

```
echo "PHP Example";
```

```
?>
```

```
</body>
```

```
</html>
```

run/check : →

localhost/code

↳ your created folder (inside the xampp)  
name

Comment Line in php : →

→ A comment in PHP code is a line i.e not executed as a part of program. Its only Purpose to be read by someone who's looking at the code.

inshort i) Let others understand your code

ii) Remind yourself of what you did

→ There are 2 ~~ways~~ commenting format i.e used in php.

a) Single Line comment : →

We can give single line comment by writing the # or // symbol

syntax <!DOCTYPE html>

```
<html>
```

```
<body>
```

```
<?php  
echo "Single line comment";  
// This is single line comment
```

```
?> </body> </html>
```

b) Multiline comment

The multiline comments can be inserted in the code by using `/* ... */`

Syntax :  $\Rightarrow$ 

```
<?php  
echo "Multiline comment"  
<?> /*  
        Multiline  
        Hello.  
        */  
?>
```

PHP Variable Tag :  $\Rightarrow$   
 $\rightarrow$  Variables in PHP are declared as `$variable name`

eg

```
$a = 10;  
echo $a;
```

Rules for Naming variable

1. Variable name must begin with a letter or underscore character.

~~2. A~~ eg

```
$a1
```

 ✓ ~~```
$1
```~~

(You can not use characters like `+, -, %, (, ), & ... etc`)

## PHP

- PHP is a server scripting language, & a powerful tool for making dynamic & interactive webpages.
- It was created by Rasmus Lerdorf in 1994 but appeared in 1995. 28 Nov.

## Notes

- PHP stands for Hypertext Preprocessor.
- PHP is an interpreted language i.e. there is no need for compilation.
- PHP is a server side scripting language, which is used to manage the dynamic content of the website.
- PHP is an object-oriented language.

## Why?

- It handles dynamic content, db as well as session tracking for the website.
  - We can create session in PHP.
  - It can access cookies variable & also set cookies.
  - It helps to encrypt the data & apply validation.
  - PHP can handle the forms such as - collect the data from users using forms, save it into the db & return useful info. to the user.
- eg Registration form

## Features

### Performance:

PHP uses its own memory, so the server workload & loading time is automatically reduced which

results in faster processing speed & better performance.

### Open Source :-

PHP source code & s/w are freely available on the web.

### Familiarity with syntax

PHP has easily understandable syntax. Programmers are comfortable coding with it.

### Embedded

PHP code can be easily embedded within HTML tags & script.

### Platform Independent

PHP is available both windows, MAC, Linux & Unix OS.

### Database Support

PHP supports all the leading db such as MySQL, SQLite, ODBC etc

### Error Reporting :-

PHP has predefined error reporting constants to generate an error notice or warning at run-time,

eg E\_ERROR, E\_WARNING, E\_STRICT, E\_PARSE

# How to Run PHP Program

PHP

- XAMPP Server

→ Install XAMPP Server

Project Location

xampp \ htdocs \ foldername \ filename.php

Open browser

localhost / foldername /

## Add 2 Numbers

```
<!DOCTYPE html>
<html>
<body>
<?php
```

```
    $a = 10;
```

```
    $b = 20;
```

```
    echo $a + $b;
```

```
?> </html> </body> </html>
```

## Datatype in PHP

PHP supports 8 datatypes which we can use to construct our variables.

### a) Integer : →

syntax \$variablename = value;

```
<?php
```

```
    $x = 10;
```

```
    var_dump($x);
```

```
?>    ↳ Return the datatype & variable
```

### b) Float / Double

syntax

```
<?php
    $a = 10.20;
```

```
    var_dump($a);
```

### c) Boolean

A boolean represents two possible states.

TRUE / FALSE.

```
$x = true;
```

```
$y = false;
```

→ It is often used in conditional testing

#### d) String

→ A string is a sequence of characters like

"Hello".

→ a string can be any text inside quotes (single quotes / double quotes).

<?php

```
$x = "Hello World";
```

```
$y = "Hello!";
```

```
echo $x;
```

```
echo "<br>";
```

```
echo $y;
```

?>

#### e) Null

→ Null is a special datatype which can have only one value: NULL.

→ A variable of data type Null is a variable that has no value assigned to it.

\* If a variable is created without a value, it is automatically assigned a value of NULL.

<?php

```
$x = "Hello World!";
```

```
$x = null;
```

```
var_dump($x);
```

?>

#### f) Array : →

An array store multiple value in one single variable.

```
$cars = array("Volvo", "BMW", "Toyota");
```

## 3/ comparison operators

↳ It is used to compare 2 values (no. or string)

<u>operator</u>	<u>Name</u>	<u>Example</u>	<u>description</u>
<code>==</code>	equal	<code>\$x == \$y</code>	Return true if <code>\$x == \$y</code>
<code>===</code>	identical	<code>\$x === \$y</code>	Return true if <code>\$x == \$y</code> & they are of same type
<code>!=</code>	Not equal	<code>\$x != \$y</code>	
<code>&lt;</code> <code>&gt;</code>	Not equal	<code>\$x &lt; \$y</code>	
<code>!==</code>	Not identical	<code>\$x !== \$y</code>	
<code>&gt;</code>	Greater than	<code>\$x &gt; \$y</code>	
<code>&lt;</code>	less than	<code>\$x &lt; \$y</code>	
<code>&gt;=</code>	greater than or equal to	<code>\$x &gt;= \$y</code>	
<code>&lt;=</code>	less than or equal to	<code>\$x &lt;= \$y</code>	

## 4) Increment / Decrement : $\Rightarrow$

↳ It is used to increment / decrement a variable's value

<u>operator</u>	<u>Name</u>
<code>++\$x</code>	pre increment
<code>\$x++</code>	post "
<code>--\$x</code>	pre decrement
<code>\$x--</code>	post decrement

2) Object  
 4) Resource → storing reference to function.

## Operators

1) Arithmetic operators  
 The PHP arithmetic operators are used with numeric values to perform common arithmetic operations, such as addition, subtraction, etc.

operator	Name	example
+	Addition	$\$X + \$Y$ $\$X = 4,$ $\$Y = 2$
-	Subtraction	$\$X - \$Y$
*	Multiplication	$\$X * \$Y$
/	Division	$\$X / \$Y$
%	Modulus	$\$X \% \$Y$
**	Exponentiation	$\$X ** \$Y$

## 2) Assignment operator →

→ It is used with numeric values to write a value to a variable.

→ The basic assignment operator in PHP is '='  
 left operand gets set to the value of the assignment expression on the right.

### Assignment

same as

$X = Y$   
 $X + = Y$   
 $X - = Y$   
 $X * = Y$   
 $X / = Y$

$X = Y$   
 $X = X + Y$   
 $X = X - Y$   
 $X = X * Y$   
 $X = X / Y$   
 $X = \$ \% Y$

additional  
at is used to perform  
dibbrent conditions.  
dibbrent actions for

$$-x''', y''', z''',$$

2  
+ 1000

Plant (5 y diots)					

✓  
1. Repetition

1. Represents the class of

work

$\rightarrow$  other character "I", "n", "on", "m"

$\frac{1}{\sqrt{e}}$

## 5) Logical operators

It is used to combine conditional statement

operator	Name	Example	Description
and	And	$\$X$ and $\$Y$	True if both $\$X$ and $\$Y$ are true
or	OR	$\$X$ OR $\$Y$	True if either $X$ or $Y$ is true
xor	XOR	$\$X$ xor $\$Y$	True if $\$X$ or $\$Y$ is true but not both

$\&\&$  And  $\$X \& \& \$Y$   
 $||$  OR  $\$X || \$Y$   
 $!$  Not  $! \$X$

## 6) String operators:-

PHP has two operators specially designed for

String

- i)  $\cdot$  → concatenation  $\$L1 \cdot \$L2$
- ii)  $=$  → assignment  $\$L1 = \$L2$  (append)

## 7) Array operators

It is used to compare array

$+$  → union  $\$X + \$Y$  union of  $\$X$  and  $\$Y$

8) conditional operator:  $\rightarrow$   
 $? : \rightarrow$  Ternary  $\$X = \text{exp1} ? \text{exp2} : \text{exp3}$   
 $\rightarrow$  true  $\rightarrow$  false

```
<?php
echo "Today is ".date("Y/m/d")."<br>";
echo "Today is ".date("Y.m.d")."<br>";
echo "Today is ".date("Y-m-d")."<br>";
echo "Today is ".date("l");
?>
```

c) else-if ladder

```
if (cond)
{
    code to be executed;
}
else if (cond)
{
    code if first cond is false;
}
else
{
    code if all cond is false;
}
```

### Loops

If you want the same block of code to run over & over again a certain no. of times. In that case we can use loop.

#### a) while loop

Loops through a block of code as long as the specified cond is true.

Syntax :-

```
while (condition)
{
    code;
}
```

```
$x = 1;
while ($x <= 5)
{
    echo "The no. is: $x<br>";
    $x++;
}
```

b) do...while

Loop will always execute the block of code once, it will then check the cond', and repeat the loop while the specified cond' is true.

Syntax :-

```
do
{
code to be executed;
}while (cond' is true);
```

```
$X = 1;
do
{
echo "The no. is : $X";
$X++;
}while ($X <= 5);
```

for loop :-

It is used when you know in advance how many times the script/code should run.

```
for (init counter; cond'; increment/decrement)
{
code;
```

```
} // for ($i = 0; $i <= 5; $i++)
```

```
{
=
}
```

Array :-

An array stores multiple values in a single variable.

Syntax :-

```
$arrayname = array (...);
```

```
$g :- $m = array (1, 2, 3, 4);
```

Print 1 to 5

$\$n = \text{array} = (1, 2, 3, 4, 5);$

$\$length = \text{count}(\$n);$  length of the element  
 $\text{for}(\$i = 0; \$i < \$length; \$i++)$

$\{ \text{echo } \$n[\$i] . " " ;$

$\}$

→ In PHP there are 3 types of arrays

a) indexed arrays → array with numeric index

b) Associative arrays

→ arrays with named keys

c) Multidimensional arrays → containing one or more arrays.

a) Indexed Array:—

There are 2 ways to represent index array  
i)  $\$cars = \text{array}('valvo', 'BMW');$

ii) Index can be assigned manually

$\$cars[0] = 'valvo';$   
 $\$cars[1] = 'BMW';$

Array index always start from 0;

b) Associative Array:—

Array that use named keys that you assign to them.

i)  $\$age = \text{array}('Ram' => '35', 'Hari' => '40');$

or

ii)  $\$age['Ram'] = '35';$   
 $\$age['Hari'] = '40';$

Q19 <? php

```
$age = array("Ram" => "35", "Hare" => "40");
```

```
echo "Ram is ". $age["Ram"] . " years old";
```

```
?>
```

c) Multidimensional Array: -

Array containing one or more arrays

Name	Stock	Sold
Volvo	22	18
BMW	15	13

```
$cars = array(  
    array("Volvo", 22, 18),  
    array("BMW", 15, 13));
```

```
echo $cars[0][0] . " : In stock :
```

Sorting Array : -

~~Sort()~~

Sort() - Sort array in Ascending order

rsort() - " " in descending "

asort() - " " in ascending order (acc. to values)

ksort() - " " " " (acc. to key)

arsort() - " " " " in descending order

rrsort() - " " " " (acc. to key)

krsort() - " " " "

Post & Get method in PHP: -

<sup>is send</sup>  
Post is used to send data to a server to create / update a resource

(It not shows in http header of the website)

- Post requests are never cached
- post " do not remain in browser history / can not be bookmarked

Get → no Reload

- It is used to request data from a specified resource.
- Reload (share link)

Database

- go to browser

↳ localhost/

↳ phpmyadmin

↳ ~~database~~

- database name (create)

→ Name

No. of columns: 4

Get & Post Methods in PHP : ⇒

PHP provides two methods through which a client (browser) can send info. to the server. These methods are given below

1. Get method
2. post method

- Get & post methods are the http request methods used inside the <form> tag to send from data to the server.

- Browser (client)

↳ appl<sup>n</sup> running on a computer

computer is server.

Get method :-

→ It is used to submit the HTML form data.  
→ The data is collected by the predefined

for GET variable form processing.

→ The info. sent from an HTML form using GET method is visible to everyone in the browser's address bar, call the variable name & their values will be displayed in the URL.

→ It is not secured to send sensitive info.

eg: - localhost/geturl.php?username=xvz&bloodgroup=A+

<html>

<body>

<form action="geturl.php" method="GET">

username: <input type="text" name="username"> <br>

Blood group: <input type="text" name="bloodgroup"> <br>

<input type="submit" />

</form>

</body> </html>

Advantages :-

→ You can bookmark the page with the specific query string becoz the data sent by the get

is displayed in URL.

→ Get request can be cached

→ Get requests are always remained in the browser history.

## post method :-

→ The info. sent from an html form using the post method is not visible to anyone.

→ `$-post`

eg `localhost/posttest.php`

## Get method

`<html>`

`<body>`

`<?php`

`echo $_GET["username"]; $bty`

`echo bloodgroup is;`

`echo $_GET["bloodgroup"];`

`? </body> </html>`

`$-post`

`=`

post method

MyPage

Agent :  $\Rightarrow$

An agent can be anything that perceives its environment through sensors & act upon that environment through actuators.

$\rightarrow$  An agent runs in the cycle of perceiving, thinking & an agent can be.

i) Human agent :  $\Rightarrow$

$\Sigma$  Sensor  $\Rightarrow$  eyes, ears & other organs

~~$\Sigma$~~  Actuator  $\Rightarrow$  Hands, legs, vocal tract.

ii) Robotic agent : -

Sensor  $\Rightarrow$  camera, infrared range finder, NLP

Actuator  $\Rightarrow$  motor

iii) Software agent :  $\Rightarrow$

Byte Stream: <sup>C takes</sup> input from the collections, Array or I/O channel.  
It can read or write files containing ASCII character that ranges from 0 to 255.

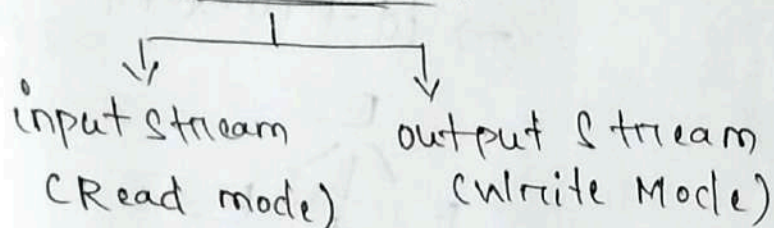

Byte Stream can copy the file containing English letters only but not of other languages.  
We can store video, audio, characters etc.

Character Stream:  $\Rightarrow$

Java supports unicode characters, byte streams fails to do the job, to overcome this character stream comes into existence.

It operates on unicode characters.

• Byte Stream

Character Stream

Output Stream class:-

Exception (Run time error)

$$10/5 = 2$$

$$\frac{10}{0} = \infty$$
