Lecture Note on Object Oriented Methodology

Diploma 2ND Year (3RD Sem)

BRANCH-CSE

*Prepared by: - Ms. Monali Patel
Senior Lecture*

Computer Science & Engineering

Programming Language :-

(1)

Language :-

→ Language is a mode of commⁿ i.e used to share ideas, opinions with each other.

→ eg :- If we want to teach someone, we need a language i.e understandable by both communicators.

What is Programming Language?

→ A PL is a computer language i.e used by programmers to communicate with computers.

eg :- C, C++, Java, Python etc.

Types of PL :-

- a) Low Level Language
- b) High Level language
- c) Middle Level language

a) Low Level language :-

Low LLL is machine dependent PL.

→ The Processor run low-level language directly without need of compiler or interpreter. (So it runs so fast.)

②
* i) ML (Machine Language) :-

4 machine code or object code.

→ Easier to read becoz ~~it is not~~ it is normally displayed in binary or hexadecimal form.

* ii) Assembly Language :-

Set of instructions in a symbolic & human-understandable form.

→ Assembler to convert AL to ML.

→ Less memory less execution time to execute program
eg :- mov 1
add 1

b) HLL :-

Designed for developing user-friendly S/W program & websites.

→ Require compiler or interpreter to translate the program into ML.

eg :- Java, C, C++, C#, etc

i) Procedural oriented PL :-

4 ~~Derived from~~ procedure call concept & it divides a program into small procedures called routines or functions.

eg:- IDE, Microsoft Visual Studio.

c, FORTRAN, Basic.

ii) OOP

↳ Based upon the objects.

→ Programs are divided into small parts called objects

eg. Java, Python

iii) Natural language:-

Part of human languages such as English, Russian, German etc.

c) MLL : →

lies betⁿ LLL & HLL

, C, C++.

Machine language

Description of compiler & Interpreter
compiler : → computer program
converts the program written in HLL to MLL

→ It translates the whole program at a time

eg Java, C.

② Interpreter :-

converts instructions line by line
written in HLL to MLL
→ It translates the program line one by
one.

* Difference betⁿ compiler & Interpreter

compiler

→ Translate the entire program at a time

Interpreter

→ Translate program line by line.

→ more memory required → less memory
→ Execution time is less → Execution time is more

→ If error detected
nothing is executed

→ If error detected

it stops &
do not go to next
line.

→ C, C++, etc.
OOP

→ Perl, Python, etc.

→ It is a methodology or Paradigm
to design a program using class &
object.

Terminology :-

(Object oriented programming)

* Difference betⁿ procedural & object op

OOPS concepts & Terminology 20.10.21

→ OOP is a programming paradigm (prototype/model) that relies on the concept of classes & objects.

→ It is used to structure a software program into a simple, reusable piece of code.

^{imp} * Features / characteristics of OOPS :-

There are main OOP concepts in Java, these are :-

- | | |
|----------------|------------------|
| a) Object | d) Polymorphism |
| b) class | e) Abstraction |
| c) Inheritance | f) Encapsulation |

a) Object:-

→ Objects are the basic run-time entities that have state & behaviour in an object oriented system.

→ An object can be defined as an instance of class.

eg:- Dogs have state (name, color, breed, hungry) & behaviour (barking, fetching, wagging tail).

b) Class:-

→ collection of objects is called class.

→ It is a logical entity.

eg:- Each bicycle was built from the same set of blueprint & therefore contains the same components.

c) Inheritance:-

→ When one object acquires all the properties & behaviour of Parent-object, it is known as inheritance.

→ It provides code reusability. It is used to achieve run-time polymorphism.

→ eg:- Dog, cat, cow can be derived class of Animal base class.

Some imp. terminology:-

i) Sub class:- The class that inherits properties from another class.

ii) Super class:- The class whose properties are inherited by sub class.

iii) Reusability:—

When we want to create a new class & there is already a class that includes some of the code that we want, we can derive our new class from the existing class. (By reusing the fields & methods of the existing class).

d) Polymorphism:— (More than one form)

→ When one task is performed by different ways i.e. known as polymorphism.

eg: → To convince the customer differently, to draw something eg. shape, or rectangle etc.

→ In Java we use Method overloading & method overriding to achieve Polymorphism.

* Dynamic Binding:—

When the type of the object is determined at run-time.

e) Abstraction: →

→ Hide internal details & showing functionality known as abstraction.

eg:— Phone call (we don't know the internal processing)

→ In Java, we use abstract class & interface to achieve abstraction.

f) Encapsulation:—

(Binding (or, Wrapping) code & data together)

into a single unit

- eg :⇒ A capsule is wrapped with different medicine
- ⇒ Java Bean (All the data members are private here,
- Provides security that keeps data & method safe from inadvertent change.
- Hiding data & method with in the object)

Benefits of oops

⇒

OOP has great advantages over other programming styles.

- a) We can eliminate redundant code & extend the use of existing class. (Through inheritance).
- b) Helps the programmer to build secure program (Principle of data hiding).
- c) Possible to have multiple objects to coexist without any interference.
- d) The object controls how one interacts with others, preventing other kinds of errors.

Applⁿ

- 1) client - Server Systems (internet)
- 2) Object oriented db
- 3) Real time System design
- 4) Simulation & modeling System

What is Java?

→ ~~James Gosling~~ 1995,

Java was developed by James Gosling in 1995

→ A general purpose object-oriented language.

→ Write once Read Any where (WORA).

→ Designed for easy web/Internet applⁿ.

→ Platform independent PL.

→ Java contains extensive library. (2500)

^{imp} * Why platform independent?

~~Beoz of~~ WORA structure makes Java as platform independent i.e. write codes in one os for example windows xp & execute that code in an other platform (os) i.e. MACOS & LINUX.

Why Java

→ Simple

→ object oriented

→ Distributed

→ Interpreted

→ Robust

→ Secure

→ Portable

→ multithreaded

History Behind Java :→

→ ~~James Gosling~~ James Gosling is the father of Java. co-founder of Java was Vinod Khosla.

→ Java was introduced in "Oak", May 20, 1995 at Sun world.

Java was categorised into 3 basic types

a) J2SE (Java 2 Standard Edition) :-

→ To develop client side stand alone appⁿ such as Thread, File IO, Swing, Applet.

b) J2ME (Java 2 Micro Edition) :-

To develop appⁿ for mobile devices such as cell phones.

c) J2EE (Java 2 Enterprise Edition) :-

To develop serverside appⁿ such as Java Servlet & Java Server Page

→ Java was originally generated by Sun Microsystems, But now Java was purchased/owned by Oracle Corporation.

How is Java different from C

⇒ Major difference is that C is a structure oriented & Java is an object oriented (class & object)

- Java doesn't support an explicit pointer type.
- Java doesn't have preprocessor, so, we can't use #define,
- Java doesn't include structures unions & enum data types.

→ Difference betⁿ c, c++ & Java

c	c++	Java
→ Procedural lang.	→ object oriented PL	→ pure OOP
2) Static PL	→ Static PL	→ Dynamic PL compilation done on runtime also.
3) code is executed directly	→ directly	→ code is executed by JVM
4) platform dependent	→ platform dependent	→ platform independent
5) uses only compiler	→ compiler	→ Both compiler & interpreter (interpreted language).
6) generate .exe & .bat, files	→ .exe	→ .class file
7) 32 keywords	→ 60	→ 52
8) .c	→ .cpp	→ .java
9) Support pointer	→ also	→ doesn't support

- | | | |
|---|--------------------------|------------------------------------|
| → It doesn't support constructors & destructors | → Both | → only const |
| → malloc(), calloc(), free(), realloc. | → new & delete operators | → garbage collector. |
| → An array should be declared with size
a[10]; | → Same | → An array can be declared without |

Execution Model of Java

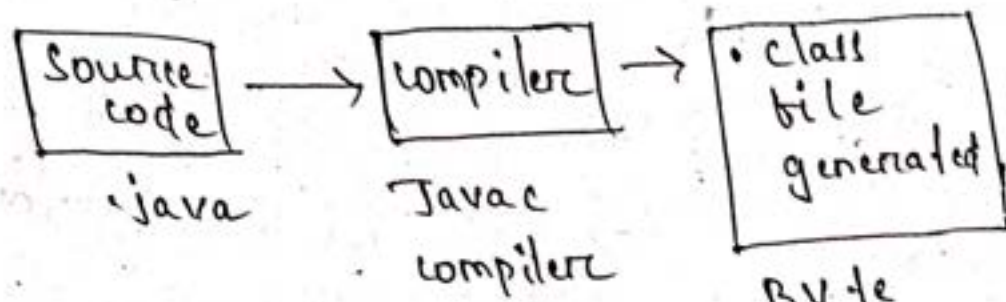

Prerequisite - B4 start - writing Java program

- 1) Setup your Work Environment.
- 2) Any sort of Notepad- to write java program
- 3) Make Sure you have The JDK installed.
- 4) Tool used for developing & testing programs written in Java & running on the Java platform.

Execution model of Java

2 steps

- a) compilation \rightarrow javac compiler
b) execution \rightarrow JVM

→ Javac compiler checks whether the syntax of the program is correct or not.

↳ If it is successful we get class file (Byte code)

Byte code :⇒ Machine independent code

↳ not

OS) readable

(we can run the code in any)

Run :-

→ Gives the class file to Java ^{class} loader

Java (classname of main method)

→ class loader loads all the classes which is required for complete info of java program

→ Byte code verifier (Run time error)

→ JIT (Just in time) compiler converts

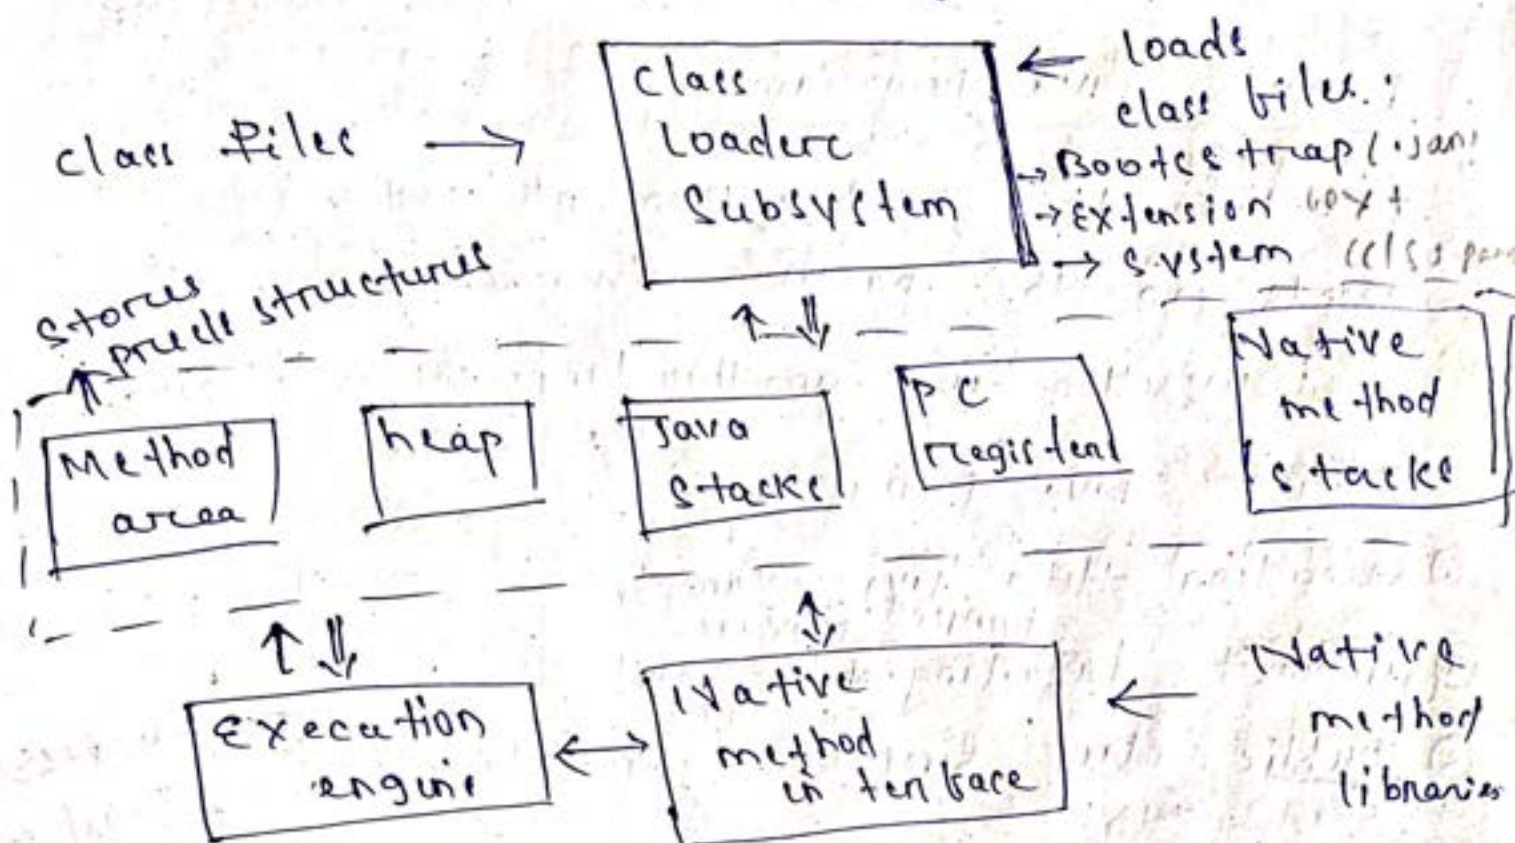

byte code to machine code.

JVM (Java Virtual Machine)

→ JVM converts Java Byte code into machine lang.

→ Architecture of JVM (Java Virtual Machine)

Architecture of JVM contains classloader, memory area, execution engine etc.

Class/Method Area:-

Store all preclass structures.

eg:- run-time const. pool

Heap stores the object

Java stack:- Methods and variables

Program counter register:-

It stores the address of the currently executing instruction by JVM

Native Method stacks

non java code (C/C++)

Native methods (JNI)

Java
me

C++
mt
{ }

Bridge (JNI)

Execution

Engine :-

Virtual processor, interpreter, compiler

Native method interface \leftrightarrow Java native lib

First Java program \Rightarrow

holds the instruction of native code

depends on the native library.

\rightarrow It is written in another lang. instead of java.

First Java program

① Creating Hello java example -

② `import java.lang.*;` ^{project package} \rightarrow All cls

③ `public class Simple` ^{/* Hello */}

④ `public static void main (String args[]) {` ^{#include <stdio.h>}

`System.out.println ("Hello");`

`}`

`printf`

① Package Declaration: \rightarrow

`Package` package name

Built in

built in or user defined

② `import` statement

`import` built in / user defined library

3> class declaration

public class → any package can be access

Main Method

- class : → Key word is used to declare a class in Java
- public : → Access Method i.e. usable to all.
- static : → There is no need to create object to create object to invoke the static method.
- The main method is executed by JVM, so it doesn't required to create object to invoke main()

void → Return type of the method, means it doesn't return any value.

main : → Startup of the program

n) String args[] : → connect line argument.

y) System.out.println : → print statement

D-1-25-10-21

variable → name of memory location whose value varies, that may or may not change.

Data type : → specifies to the compiler which kind of it is.

“+” is used to join 2 strings / concatenate

“+” is used to join 2 strings / concatenate

Data type : \Rightarrow

a) Primitive data type

b) Object / Reference data type, / Non primitive

a) Primitive Data type

\rightarrow Predefined by the programming language called as the keyword brought by the compiler.

\rightarrow There are 8 Primitive data type

i) Byte : \Rightarrow

\rightarrow Used to save space, may be in place of integer becoz a byte is 4 times smaller than an integer.

\rightarrow 8 bit signed (may be -ve or +ve)

\rightarrow -128 to 127 eg : - byte `a = 10;`

ii) Short

\rightarrow 16 bit signed 2's complement integer

\rightarrow -32768 to +32767 eg `Short a = 324;`
`Short n = -5000;`

\rightarrow Save space (2 times smaller than integer)

iii) Integer

\rightarrow 32 bit signed 2's complement integer

\rightarrow -2147483648 to 2147483647

\rightarrow Default value is zero \rightarrow eg `int a = 30;`

iv) Long

64 bit signed 2's complement integer

→ -9223372036854775808 to 9223372036854775807

→ ^{used in} wider range than integer

→ Default value is 0L

→ $x = 9567890L$

eg long $m = 10000L$;

v) Float

→ It is a single precision, 32 bit IEEE 754 floating point.

→ Float mainly used to save memory in large array of floating point no.

→ default value is 0.0f

→ Never used for precision value such as currency

→ eg $x = 259.5f$ float $F1 = 234.5f$;

vi) Double

→ Double precision IEEE 754 floating point

→ 0.00 double $a = 12.3$;

vii) Boolean : →

→ one bit information datatype used for logical aspects.

→ 2 value True/False boolean $a = True$;

→ Default value is false

eg boolean $x = True$

viii) char

- Single 16 bit unicode char.
- \u0000 to \uFFFF char letters = 'A'.
- 'char' is used to store any character.

WAP to add two no.

```
class Add
```

```
{  
    public static void main (String args[])
```

```
{  
    int a = 10, int b = 20;
```

```
    int c = a + b;
```

```
    System.out.println("sum is = " + c);
```

```
}
```

```
}
```

WAP to Print a character / string

```
public class A
```

```
{
```

```
    public static void main (String args[])
```

```
{
```

```
    char a1 = 'a';
```

```
    char a2 = 'b';
```

```
    System.out.println("char 1: " + a1);
```

```
    System.out.println("char 2: " + a2);
```

```
}
```

```
}
```

b) Non Primitive data type

c) user defined data type

4 types of primitive data type

i) Array:-

→ used to store data in consecutive manner

ii) String:-

→ used to store consecutive characters

String abc = "Hello";

iii) class

iv) Interface

Variable : →

A name of the reserved area allocated in memory. (Name of the memory location)

in → data = 50;
 ↓
 variable

3 types of variable

a) Local variable (inside the body of the method)

b) Instance variable / Non-static variable

c) static variable (inside the class but outside the body of the method)

↓
declared as static

Public class A

{

Static int m = 100; // → Static Variable

void method()

{
 int n = 90; // local Variable
 int m = 201; int s = m + n;
}

public static void main (String args[]

{

int data = 50; // instance Var

int int b = m + data;

}

}

Operator

Symbol i.e. used to perform operation

→ unary operator

→ Arithmetic operator

→ Shift operator

→ Relational operator

→ Bitwise operator

→ Logical operator

→ Ternary operator

→ Assignment operator

a) unary operators

→ Java unary operators requires only one operand.

operation : →

a) postfix (exp++ / exp--)

b) prefix (++exp / --exp)

eg : → int a = 10;

(++a); → 11

(a++) → 11 (12)

--a → 11

(a--) → 11 (10)

a++ = a+1

a++

11

12

11

10

a

Program for unary operators

class unary

{

public static void main (String args[])

{

int a = 10;

System.out.println(a++); → 10 (11)

System.out.println(++a); → 12

(a--); → 12 (11)

(--a); → 10

a = 10 (11)

a++ → 10 (11)

a++ (11)

Arithmetic operators :-

It is used to perform addition, sub, multiplication & division (Basic mathematical operations)

3, 15, 3rd 11

```
c = a + b;
System.out.println("c");
```

```
}
```

```
}
```

~~for double~~

next + Double() → for double next + Boolean() → boolean
 next + Float() → float next + Short() → short
 next + Line() → String
 next + Long() → long

WAP to print a person's Age, Name & salary by using Scanner class.

c) Logical operators:-

When we want to form compound by combining two or more Relation.

→ & &, ||, !.

→ Logical expression defer a value of true or false.

OP 1	OP 2
T	T
T	F
F	T
F	F

OP 1 OP 2
T
T
T
F

& &
T
F
F
F

d) Relational operators

→ It is used in the case of comparison

3 > 5 use 3 and 5

=, !=, >, <, <=, >= $\swarrow \searrow$

True / false

int a = 5, b = 6;

System.out.println(a > b);

Logical OR / & & operations

(10)

int a = 10, b = 6, c = 15;

System.out.println(a > b & & a > c);

e) Shift operators:-

<<, >> → Right shift

<<, >> → Left shift

public class

Shift

public static void main(String args[])

{
int a = 8; → 1000

int b = a << 2; ⇒ Extra 0's

int b = a >> 2; ⇒ cut the Right

value

8 ⇒ 1 0 0 0 0 0 0 0 → 32

add extra 2's

8 ⇒ 1 0 0 0

>> 2 ⇒ 10.

25 ⇒ a = 11001

a << 2 ⇒ 1100100 (add 2's)

>> 2 ⇒ 110 (cut 0)

#7) Bitwise operators
→ execute single bit on their operands.

1. \Rightarrow OR (Bitwise)

Q Bitwise AND

Q = Bitwise AND Assignment

1 = Bit wie 0 R

$$\wedge \rightarrow \text{XOR (Exclusive OR)}$$

$\angle C \rightarrow$ let's check

→ Right shift

2 \rightarrow one's complement

$$5 + a = 5 \therefore, 5 + b = 7$$

今

$$\underline{0.101}$$
 \hat{a}

0 1 1

xor

$$\begin{array}{r} 0 - 0 = 0 \\ 1 - 1 = 0 \end{array}$$

2 → single
~ a

$$\frac{a}{0} \rightarrow \infty$$
$$\frac{b}{0} = \frac{1}{1}$$
$$\begin{array}{r} 8 \\ 0 \\ 1 \\ 0 \\ \textcircled{0} \\ 5 \end{array}$$
$$\frac{1}{0.01} = 100$$
$$\frac{1}{0} \frac{1}{1} 0$$

9

0
1
1
0

$$\begin{array}{r} 0 \ 1 \ 0 \ 1 \\ + \quad \quad \quad 1 \\ \hline 0 \ 1 \ 1 \ 0 \end{array}$$

5. $a = 5, b = 7;$

```

in + a = 5, b = 1;
system.out.println ( a & b );

```

 $(a|b);$

a) b)

$(\sim a) \wedge b$

$\frac{1}{32}$ $\frac{0}{16}$ $\frac{0}{8}$ $\frac{0}{4}$ $\frac{0}{2}$ $\frac{0}{1} \rightarrow 32$
 $\frac{1}{32}$ $\frac{0}{16}$ $\frac{0}{8}$ $\frac{4}{4}$ $\frac{2}{2}$ $\frac{1}{1} \rightarrow 2$

2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100

{} Ternary operator

conditional operator

$\text{var} = (\text{cond}) ? \text{value 1} : \text{value 2}$
 \rightarrow if true \rightarrow if false

$\text{min}(a < b) ? a : b ;$

$a = 2$

$b = 5$

$\text{min} = 2 < 5 : 2$

$a + 4$
 $\underline{a = a + 4 ;}$

h) Assignment operator :

Assign value on the right to the operator on the left

$a = 10 ; \quad b = 20$

$a + 4 ; \quad a = a + 4$

$b - 4 ; \quad b = b - 4$

$a \neq 4$
 $a = a + 4$

Type casting : TYPE conversion

\rightarrow converting one primitive datatype into another primitive datatype is called primitive ~~data type~~ casting / conversion.

$\text{int } a = 5 ;$

$\text{double } b = 2.7 ;$

$\text{int } c = a + b ; \quad 5 + 2$

$\text{double } c = 5.0 + 2.7$

WAP to calculate division

WAP to find max^m of 3 no. using
nested if else statement

class Test

{

public static void main (String args[])

{

int a = 6, b = 5, c = 13;

if (a > b) && (a > c)

{
System.out.println("a is large")

}
else if (b > a) && (b > c)

{
System.out.println("b is large")

}

}

else

{

System.out.println("c is large")

}

}

}

WAP to calculate division obtained by a student with his % mark given

a = 76;

if (a > 60);

{
1st;

{
2nd

}

else {
3rd

9/11/21

Switch Statement:-

- The Switch " is Java's multi way branch statement.
- It is a case/selection oriented statement where among the alternative we have to choose a single alternative.
- It is better than nested if else and if-else ladder statement.

← user define variable or const.

Syntax

Switch (choice / expression)

{

case 1:

S1 sequence;

break; ← may or may not be

case 2:

// statement sequence;

break;

⋮

default:

S1:

⋮

Sn

}

int number = 20;

Switch (number)

{

case 10:

System.out.println("10");

break;

case 20:

("20");

break;

case 30:

("30");

break;

default :
c.o.p ("Not 10, 20 or 30");
}

- Note : →
- i) There can be one or N no. of case value must be literal.
 - ii) The case value must be switch exp. type only. i.e. it doesn't allow variable.
 - iii) The case value must be unique. In case of duplicate, it renders compile time error.
 - iv) Each case statement can have a break statement which is optional. When controls reach to break it ~~break~~ jumps the controls after switch.

Jump Statement :-

Jump statement makes the control jump to another section of the program.

i) Break statement : → Takes control out of the loop.

ii) continue statement → Takes control the beginning of the loop.

iii) go to statement → To desired line of program

iv) Return

Class : \Rightarrow

- \Rightarrow class is a rule or structure using that structure we give real life existence / implementation.
- \Rightarrow class is a template or blueprint from which objects are created.
- \Rightarrow Every thing we wish to represent in a Java program must be encapsulated in cls.
- \Rightarrow cls defines the state & behaviour of the basic programming components known as objects.
- \Rightarrow cls creates objects & objects use methods to communicate betⁿ them. (All about OOP)

eg : \Rightarrow

<u>class</u>	<u>properties</u>	<u>Behaviour</u>
Human	Height Weight color Name	eat talk sleep

Anatomy / Syntax of cls : \Rightarrow

modifier class classname

```
{  
    Access level    datatype    variable name;  
    {  
        datatype    method name (P1, P2)  
        ≡  
    }  
}
```

2

4516 factorial of no.

```
class Fact
```

```
{ public static void main (String[] args)
```

```
{ int n=5, fact=1;
```

```
while (n >= 1)
```

```
{ fact = fact * n;
```

```
n--;
```

```
}
```

```
System.out.println (fact);
```

```
}
```

Static block, Method, variable

variable \Rightarrow static print

2 ways

- i) we can directly access
- ii) with the help of class name

Static
Related to cls

\rightarrow indicates that the particular member belongs to a type itself, mainly used to help memory management.

1 copy only (not change in cls)

eg. name
breed: Homo

As - No value changes in static

applied in variable, cls, method, blocks,
nested cls

Final

Static keywords can't be declared in
non static cls.

* We can write static in main cls

\rightarrow We can't write non-static method in
static method.

Jump statement:-
 ↳ Transfers Program execution control to a specific statement.

a) Break : \Rightarrow

class A

{ psvm(...)

{ for(int i=0; i<10; i++)

{ if(i==5)

{ break;

} s.o.p(i);

} s.o.p("outside");

}

0
1
2
3
4

b) continue : \rightarrow It is used within looping statements.

class A

{ psvm(String args[])

{ for(i=1; i<10; i++)

{ if(i%2==0)

{ continue;

} s.o.p(i);

1
3
5
7
:
:
:
99

Return

It is mainly used in methods in order to terminate a method in betⁿ & return back to the caller method

```
class A
{
    double add(double a, double b)
    {
        double sum = 0;
        sum = (a+b) / 2.0;
        return sum;
    }
}
```

Syntax : \rightarrow ^{return}
return

Program : \rightarrow

```
returnvalue;
public class A
{
    int compare()
    {
        int x = 3;
        int y = 8;
        S.o.p("X = x + y = +y");
        if (x > y)
            return x;
        else
            return y;
    }
}

public class B
{
    A ob = new A();
    int R = ob.compare();
    S.o.p(R);
}
}
```

Loop in Java

- Looping repeatedly execute the same set of instruction until a termination condⁿ is met.
- It reduces the programming effort for execution of similar statement for a no. of time or infinitely time.
- (or) If we want to repeat one statement multiple times, in that case we can simply use loop/iteration statement.
- Loops must have a starting point it may or may not have ending point.

Types

a) while loop :

- It is used to iterate a part of the program several times.
- If the no. of iteration is not fixed, it is recommended to use while loop.

Syntax :⇒

while (condition)

{

code to be executed ;

increment / Decrement (may or may not)

}

Q. Write to print 1 to 10.

Ans: ~~Prog~~

public class → A

```
{ public static void main(String args[])
```

```
{ int i = 1;
```

```
  while (i <= 10)
```

```
  { System.out.println(i);
```

```
    i++;
```

```
  }
```

```
}
```

```
}
```

Infinite loop using while

public class infinite

```
{ public static void main(String a[])
```

```
{ while (true)
```

```
{ System.out.println("Infinite loop");
```

```
}
```

```
}
```

```
}
```

Flowchart

b) do-while Loop

→ It is used to iterate a part of the program several times.

→ If the no. of iteration is not fixed & you have to execute the loop at least once, it is recommended to use do-while loop.

→ Java do-while loop is executed at least once before condⁿ is checked after loop body.

Syntax :-

```
do
{
  code to be executed ;
  increment / Decrement
} while (condition)
```

Flowchart :-

Q write a program to print 1 to 10 using do-while

public class → A

```
{
```

```
  public static void main(String args[])
```

```
{
```

```
  int i;
```

```
do
{
    System.out.println(i);
    i++;
} while (i <= 10)
```

Java infinite loop

```
do
{
    System.out.println("infinite loop");
} while (true)
```

C) For loop

- The java for loop is used to iterate a part of the program several times.
- If the no. of iteration is fixed, it is recommended to use for loop.
- It consists of 3 parts

i) Initialization :

- It is the initial condⁿ, which is executed once when the loop starts
- Here, we can use an already initialized variable or we can initialize a variable.

ii) Condition :

- It continues execution until the condition is false.
- It must return boolean value i.e. either true/false.

iii) Increment/Decrement :

- It increments or decrements the value.

Syntax

for (initialization; condition; incre/decre)

{
Statement to be executed;
}

Flowchart

Q. WAP to print 1 to 10 using

public class A

```
{ public static void main(String args[])
```

```
{ for(int i=1; i<=10; i++)
```

```
{ System.out.println(i);
```

```
}  
}  
}
```

Pyramid

- i

```
*  
* *  
* * *  
* * * *  
* * * * *
```

for(int i=1; i<=5; i++) ← Row

```
{ for(int j=1; j<=i; j++) ← column
```

```
{ System.out.println(" ");
```

```
}
```

```
System.out.println(); ← newline
```

```
}
```

```
* * * * *
```

```
* * * *
```

```
* * *
```

```
* *
```

```
*
```

```
for(int i=1; i<=5; i++)
```

```
{ for(j=5; j>=i; j--)
```

```
{ System.out.println(" ");
```

```
}
```

```
System.out.println();
```

```
}
```

Java Infinite loop

```
for(;;)
```

```
{ System.out.println("Infinite loop");
```

```
}
```

1

1 2

1 2 3

1 2 3 4

1 2 3 4 5

```
for(i=1; i<=5; i++)
```

```
{ for(j=1; j>=i; j++)
```

```
{ S.o.p(j);
```

```
}
```

```
S.o.p();
```

```
}
```

```

1
2 2
3 3 3
4 4 4 4
5 5 5 5 5

```

```

for(i=1; i<=5; i++)
{
    for(j=1; j<=i; j++)
    {
        s.o.p(i);
    }
    s.o.p(i);
}

```

Array Class

- class is a Rule or Structure using that structure we give real life existence/implementation.
- class is a template or blueprint from which objects are created.
- Everything we wish to represent in a Java program must be encapsulated in class.
- class defines the state & behaviour of the basic programming components known as objects.
- class creates objects & object use methods to communicate with them.

eg	class	Properties/State	Behaviour
	Human	Height Weight Color etc	eat talk sleep

Anatomy / Syntax of class

```

<access specifier> class class-name
{
    <data-type> variable-name;
    <return-type> method-name(P1, P2)
}

```

Array in Java

An array is a collection of similar type of elements which has contiguous memory location.

- Array in Java is index-based. The first element of the array is stored at the 0th index, 2nd element is stored in 1st index and so on.

0	1	2	3	4	5
25	56	79	53	45	10

int [] A

Advantages

- code optimization: It makes the code optimized, we can retrieve or store the data efficiently.
- Random Access: we can get any data located at an index position.

Disadvantages

- Size limit :- we can store only the fixed size of element in the array.
→ It doesn't grow its size at runtime.

Syntax to write array

- ```
1) datatype[] arrayname;
eg int[] a;
2) arrayname = new datatype[size];
eg regdno = new int[5];
3) datatype[] arrayname = new datatype[size];
eg int[] regd = new int[5];
```

## Types of array

Arrays are classified into two types,

- 1) Single Dimensional (1D) [ ]
- 2) Multidimensional [ ][ ]

### 1) Single Dimensional :-

- ```
eg class A  
{  
    public static void main(String args[])  
    {  
        int a[] = new int[5];  
        a[0] = 10;  
        a[1] = 20;  
        a[2] = 30;
```

```
a[3] = 40;  
a[4] = 50;
```

```
for (i = 0; i < a.length; i++)  
{  
    System.out.println(a[i]);  
}
```

Direct Initialization

```
public class A  
{  
    public static void main(String args[])  
    {  
        int a[] = {33, 3, 4, 5, 1};  
        for (int i = 0; i < a.length; i++)  
        {  
            System.out.println(a[i]);  
        }  
    }  
}
```

for-each loop for Java Array

we can also print the Java array

Using for-each loop.

↳ print array element one by one

Syntax

```
for (data-type : array)
```

```
{  
    body;  
}
```

```

29 class Arrayexp
{
    public static void main(String args[])
    {
        int arr[] = {33, 11, 22};
        for (int i : arr)
            System.out.println(i);
    }
}

```

User Input : →

```

import java.util.Scanner;
class Test-array
{
    public static void main(String args[])
    {
        int [] ah = new int[5];
        S.o.p("Enter value to array");
        Scanner sc = new Scanner(System.in);
        for (int i = 0; i < 5; i++)
        {
            ah[i] = sc.nextInt();
        }
        System.out.println("values of array are");
        for (int i = 0; i < 5; i++)
        {
            S.o.p(ah[i]);
        }
    }
}

```

Demonstration of character Array

```

class char-array
{
    public static void main(String args[])
    {
        char [] ah = {'m', 'e', 'g', 'h', 'a'};
        System.out.println("values of array are");
        for (int i = 0; i < 5; i++)
        {
            System.out.println(ah[i]);
        }
    }
}

```

Finding Maximum Element in an Array

```

import java.util.Scanner;
class Max-array
{
    public static void main(String args[])
    {
        int [] g = new int[5];
        System.out.println("Enter value to array");
        Scanner sc = new Scanner(System.in);
        for (int i = 0; i < 5; i++)
        {
            g[i] = sc.nextInt();
        }
        int max = g[0];
        for (int i = 1; i < 5; i++)
        {
            if (max < g[i])

```

```

    { max = g[i];
  }

```

S.o.p ("The max element of the array is " + max);

Finding Sum of the element of an Array

```

import java.util.Scanner;

```

```

class Sum-array

```

```

{ public static void main (String args[])

```

```

{ int[] g = new int[5];

```

```

  System.out.println ("Enter values");

```

```

  Scanner sc = new Scanner (System.in);

```

```

  for (i = 0; i < 5; i++)

```

```

  { g[i] = sc.nextInt();

```

```

  }

```

```

  int sum = 0

```

```

  for (i = 0; i < 5; i++)

```

```

  { sum = sum + g[i];

```

```

  }

```

S.o.p ("The sum is " + sum);

Multidimensional Array

In Java multidimensional arrays are actually array which is achieved by adding more square bracket.

→ A 2D array can be like a table or matrix of rows and columns.

Syntax

a) Declaration Syntax

datatype[][] arrayname = new datatype[rows][columns];

eg:-

```

int[][] a = new int[2][2];

```

b) Initialization

arrayname[rows][columns] = value;

eg array[0][0] = 1;

c) Direct Method

```

int[][] arrayname = { { }, { } };

```

```

int[][] a = { { 2, 3 }, { 4, 5 } };

```

```

import java.util.Scanner;

```

```

class TwoD-array

```

```

{ public static void main (String args[])

```

```

{ int[][] a = new int[2][2];

```

Scanner sc = new Scanner(System.in);
 S.o.p << "Enter the element of matrix";

for (int r = 0; r < 3; r++)

{
 for (int c = 0; c < 2; c++)

{
 a[r][c] = sc.nextInt();

}

}

S.o.p << "The elements are";

for (int r = 0; r < 3; r++)

{
 for (int c = 0; c < 2; c++)

{
 S.o.p (a[r][c] + " ");

}

S.o.p ();

}

}

}

a[0][0]	a[0][1]
2	1
a[1][0]	a[1][1]
4	3
a[2][0]	a[2][1]
5	4

class Testarray

{
 public static void main (String arg[])

{

int a[][] = {{1, 2, 3}, {2, 4, 5}, {3, 4, 6}};

for (int r = 0; r < 3; r++)

{

for (int c = 0; c < 3; c++)

{
 S.o.p (a[r][c] + " ");

}

S.o.p ();

}

}

Addition of 2 Matrices in Java

class Test-array2

{
 public static void main (String arg[])

{

int a[][] = {{1, 3, 4}, {3, 4, 5}};

int b[][] = {{1, 3, 4}, {3, 4, 5}};

int c[][] = new int[2][3];

for (int r = 0; r < 2; r++)

{

for (int c = 0; c < 3; c++)

{
 c[r][c] = a[r][c] + b[r][c];

S.o.p (c[r][c] + " ");

S.o.p ();

3
3
3

$$\begin{bmatrix} 1 & 3 & 4 \\ 3 & 4 & 5 \end{bmatrix}_{2 \times 3} + \begin{bmatrix} 1 & 3 & 4 \\ 3 & 4 & 5 \end{bmatrix}_{2 \times 3}$$

$$\begin{bmatrix} 2 & 6 & 8 \\ 6 & 8 & 10 \end{bmatrix}_{2 \times 3}$$

Multiplication of Matrices

$$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix} * \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}$$

$$= \begin{bmatrix} 1*1 + 1*2 + 1*3 & 1*1 + 1*2 + 1*3 & 1*1 + 1*2 + 1*3 \\ 2*1 + 2*2 + 2*3 & 2*1 + 2*2 + 2*3 & 2*1 + 2*2 + 2*3 \\ 3*1 + 3*2 + 3*3 & 3*1 + 3*2 + 3*3 & 3*1 + 3*2 + 3*3 \end{bmatrix}$$

$$= \begin{bmatrix} 1+2+3 & 6 & 6 \\ 2+4+6 & 12 & 12 \\ 18 & 18 & 18 \end{bmatrix}$$

$$= \begin{bmatrix} 6 & 6 & 6 \\ 12 & 12 & 12 \\ 18 & 18 & 18 \end{bmatrix}$$

public class matrixmul

{ public static void main (String args[])

{ int a[][] = {{1,1,1},{2,2,2},{3,3,3}};
int b[][] = {{1,1,1},{2,2,2},{3,3,3}};
int c[][] = new int [3][3];

for (i=0; i<3; i++)

{ for (j=0; j<3; j++)

{ c[i][j] = 0;

for (int k=0; k<3; k++)

{ c[i][j] += a[i][k] * b[k][j];

}
System.out.println(c[i][j]);

}
System.out.println();

}
}

Object

- Instance of a class is called object.
- An object in Java is essentially a block of memory that contains space to store variable (class does not reserved memory).
- Objects in Java are created using

new operator

↳ used to assign memory

Syntax for object creation

- ① `classname objectname;`
`objectname = new classname();`
- ② `classname objectname = new classname();`

eg:- class A
{
 static int n, m;
 public static void main(String args[])
 {
 A ob = new A();
 ob.n = 10;
 ob.m = 20;
 System.out.println(n);
 System.out.println(m);
 }
}

Methods in Java

- A method is a block of code which only runs when it is called.
- You can pass data, known as parameters/arguments.
- Methods are used to perform certain actions & they are also known as functions.

create a Method

- A method must be declared within a class.
- It is defined with the name of the method, followed by parenthesis ().

Syntax

access	return	method	← may/may not
Specifier	type	name	(parameters...)

eg `public int add(int a, int b)`

Addition of 2 no. using Method

```
public class method_add  
{  
    public static void add()  
    {  
        int a = 20, b = 30;  
        int c = a + b;
```

```
System.out.println("The sum is : " + c);
}

public static void main (String args[])
{
    add();
}
```

Types of Method

There are 2 type of method

- a) Predetermined Method
- b) Userdefined Method

a) Predefined / Built-in Method :-

The method i.e already defined in Java class libraries.

→ We can directly use that method just by calling them in the program at any point.

19 → length(), equals(), compareTo(), sqrt(), max(), etc

↳ concat(): It concatenate 2 strings
 s1.concat(s2);

4 charAt(i): Returns a character by index position
 S1.charAt(i);

↳ tolowercase() :- convert value to upper case

Sl. to Upper Face () ;

4) tolowercase() :- convert value to lowercase

↳ trim(): Remove space from both side of a string. eg str.trim();

↳ abs(): Return absolute value
eg Math.abs(value);

4) round(): It round the value to nearest integer.

19 Math.round(a);
4 min() / max() :

4 min() / max() :

- Access Modifiers in Java :-

→ Access modifier in java helps to restrict the scope of a class, constructor, variable, method or data members.

→ 34 species the accessibility

→ There are 4 types of access modifier used in Java

- 1) private
- 2) default
- 3) public
- 4) Protected

1- Private :->

The access level of a private modifier is only within the class. It can't be accessed from outside the class.

-> A Subclass/child class does not inherit the private members of its parent class.

B.java

```
class A
{
    private int d = 40;
    private void msg()
    {
        System.out.println("Hello");
    }
}

class B
{
    public static void main (String args[])
    {
        A ob = new A();
        System.out.println (ob.d); // compile
        System.out.println (ob.msg()); // compile time error
    }
}
```

Note :->

If you make any class constructor private, you can not create the instance of that class from outside of the class.

constructor :-

It is block of code similar to the method. It is called when instance of a class is created.

B.java -> It is a special type of method which is used to initialize the object.

```
class A
{
    private A()
    {
        void msg()
        {
            System.out.println("Hello");
        }
    }
}

public class B
{
    public static void main (String args[])
    {
        A ob = new A(); // compile time error
    }
}
```

Note

A class can not be private or protected except nested class.

2) Default :-

If we don't use any modifier, it is treated as default by default.

-> The default modifier is accessible only within the program.

-> In the below example, we have created two packages pack & mypack. we are

accessing the class A from outside its package, since A class is not public, so it cannot be accessed from outside the package.

```
A.java
package pack;
class A
{
    void msg()
    {
        System.out.println("Hello");
    }
}
```

```
B.java
package mypack;
import pack.*;
class B
{
    psvm(...)
    {
        A ob = new A();
        ob.msg();
    }
}
```

3) Protected
 → The protected access modifier is accessible through inheritance only.
 → The protected modifier can be applied on the datamember, method & constructor.
 * It can't be applied on the class.

```
A.java
class A
{
    protected void msg()
    {
        System.out.println("Hello");
    }
}
```

```
B.java
class B extends A
{
    public static void main(String args[])
    {
        B ob = new B();
        ob.msg();
    }
}
```

4) public
 The public access modifier is accessible everywhere.
 → It has the widest scope among all other modifiers.

```
A.java
class A
{
    public void msg()
    {
        System.out.println("Hello");
    }
}
```

```
B.java
class B extends A
{
    public static void main(String args[])
    {
        B ob = new B();
        ob.msg();
    }
}
```

All Java Access Modifiers

Access modifier	within class	within package	outside pkg by subclasses only (inheritance)	outside package
private	Yes	No	No	No
Default	Yes	Yes	No	No
protected	Yes	Yes	Yes	No
public	Yes	Yes	Yes	Yes

String

String

- In Java, String is a sequence of characters.
- String is basically an object that represents sequence of char values.
- The java.lang.String class is used to create String object.

```
String s1 = "Java";
String s2;
```

```
s2 = s1;
```

```
System.out.println(s2);
```

class TestString

```
{
    public static void main(String args[])
    {
        char[] ch = {'H', 'e', 'l', 'l', 'o'};
        for (int i = 0; i < ch.length; i++)
        {
            System.out.println(ch[i]);
        }
    }
}
```

class TestString2

```
{
    public static void main(String args[])
    {
        String s1 = "Hello";
        System.out.println(s1);
    }
}
```

How to create String object?

There are 2 ways to create String object:

1. By String Literal
2. By new keyword

1. String Literal:

```
String s = "welcome";
```

→ String objects are stored in a special memory area known as String constant pool.

2. New keyword:

```
String s = new String("Hello");
```

String-ex.java

```
public class String-ex
{
    public static void main(String args[])
    {
        String S1 = "Hello";
        char ch[] = {'H', 'e', 'l', 'l', 'o', '\0'};
        String S2 = new String(ch);
        // converting char to string

        String S3 = new String("Good");
        System.out.println(S1);
        System.out.println(S2);
        System.out.println(S3);
    }
}
```

Java StringBuffer class:

Java StringBuffer class is used to create mutable (modifiable) String.

→ The StringBuffer class in Java is same as String class except it is mutable i.e. it can be changed.

Constructors of StringBuffer class

1. StringBuffer(): Creates an empty String buffer with the initial capacity 16.

2. StringBuffer(String str): Create a String buffer with the specified String.

3. StringBuffer(int capacity): Create an empty String buffer with specified capacity as length.

Mutable String:

→ A String that can be modified or changed is known as mutable String.

1) append() method

The append() method concatenates the given argument with the String.

class A

```
{
    public static void main(String args[])
    {
        StringBuffer sb = new StringBuffer("Hello");
        sb.append("Good Morning");
        System.out.println(sb);
    }
}
```

2) StringBuffer insert() method:

The insert() method inserts the given String with this String at the given position.

class Str-insert

```
{
    public static void main(String args[])
    {
        StringBuffer sb = new StringBuffer("Hello");
```

```
        sb.insert(1, "Java");
        System.out.println(sb);
    }
}
```

3) StringBuffer replace() method

The replace() method replace the given String from the specified beginIndex & endIndex

```
class Str-replace
{
    public static void main(String args[])
    {
        StringBuffer sb = new StringBuffer("Hello");
        sb.replace(1, 3, "Java");
        System.out.println(sb);
    }
}
```

4) delete() method

The delete() method of StringBuffer class delete the string from the specified beginIndex to endIndex

eg Str-delete.java

```
class Str-delete
{
    public static void main(String args[])
    {
        StringBuffer sb = new StringBuffer("Hello");
        sb.delete(1, 3);
        System.out.println(sb);
    }
}
```

5) reverse() method

The reverse() method of StringBuffer class reverse the current string.

Str-reverse.java

```
class Str-reverse
```

```
{
    public static void main(String args[])
    {
        StringBuffer sb = new StringBuffer("Hello");
        sb.reverse();
        System.out.println(sb);
    }
}
```

Difference betⁿ String Buffer & Builder

- | | |
|--|-------------------------------------|
| <u>StringBuffer</u> | <u>StringBuilder</u> |
| → StringBuffer is Synchronized i.e. thread safe. It means two threads can't call the methods of StringBuffer simultaneously. | → StringBuilder is non-synchronized |
| → Less efficient | → more efficient |

Parameter passing:

There are different ways in which parameter data can be passed into & out of method.

Types of parameters

a) Formal Parameter

- A variable & its type as they appear in the prototype of the method or method.

Syntax

funⁿ name (data-type variable-name)

b) Actual Parameter:

The variable or expression corresponding to a formal parameter that appears in the method in the calling environment.

Syntax

funⁿ name (variable(s));

or values that are passed to a method when it is invoked

eg:

```
void add(int x, int y)
{
    int z = x + y;
    System.out.println("Z");
}
add(2, 3);
add(5, 4);
```

Formal Parameters
Actual Parameters

Important Method for Parameter passing

1. Pass By Value / call by value:-

- call by value means calling a method with a parameter as value.
- The argument value is passed to the parameter.

eg:

```
public static void main(String args[])
{
    sum(1, 2);
}
public static int sum(int x, int y)
{
    return x + y;
}
```

Constructors:-

- A constructor is a special member function/method/procedure/operation/behaviour/action of a class i.e. used to create object of that class.
- It has same name as the class itself.
- It has no return type & is invoked or called using new operator.

Syntax:-

modifier classname (data-type variable...)

{
Statement 1;

⋮

Statement n;

}

-A.java

```
29 public class A
{
    public static void main(String args[])
    {
        A ob = new A();
    }
    A()
    {
        System.out.println("constructor is called");
    }
}
```

192

-A1.java

```
public class A1
{
    A1()
    {
        System.out.println("A1 ob");
    }
    public void show
    {
        System.out.println("Good morning");
    }
    public static void main(String args[])
    {
        A1 ob = new A1();
        ob.show();
    }
}
```

Types of Java constructors:-

There are two types of constructors in Java.

1. Default constructor
2. Parameterized constructor

1. Default constructor:-

→ A constructor is called default constructor when it does not have any parameter.

Syntax

```
classname()
{
    ≡
}
```

add.java

```
19: class add
{
    add()
    {
        int c = 10+20;
        System.out.println(c);
    }
    public static void main (String args[])
    {
        add ob = new add();
    }
}
```

Purpose

It is used to provide the default value to the object like 0, null etc

```
20: class Student
{
    int Regd;
    String name;
    void display()
    {
        S.o.p.c < Regd + " " + name;
    }
    public static void main (String args[])
    {
        Student s1 = new Student();
        Student s2 = new Student();
        s1.display();
        s2.display();
    }
}
```

Note
If there is no constructor in a class, compiler automatically creates a default constructor.

2. Parameterized constructor:-
A constructor which has a specific number of parameter is called a parameterized constructor.

Add.java

```
19: public class Add
{
    Add (int m, int n)
    {
        System.out.println(m+n);
    }
    public static void main (String args[])
    {
        Add ob = new Add (10, 20);
    }
}
```

Add.java

```
public class Add1
{
    Add1 (int m, int n)
    {
        System.out.println(m+n);
    }
    void add (int a, int b)
    {
        System.out.println(a+b);
    }
}
```

```

public static void main(String args[])
{
    Addl ob = new Addl(10, 20);
    ob.add(20, 30);
}
}

```

Constructor overloading

Constructor overloading in Java is a technique of having more than one constructors with different parameter lists.

```

eg
class Student
{
    int id;
    String name;
    int age;
    Student(int i, String s)
    {
        id = i; name = s;
        System.out.println(id + " " + name);
    }
    Student(int i, String s, int ag)
    {
        id = i;
        s = name;
        ag = age;
        System.out.println(id + " " + name + " " + age);
    }
}

```

```

public static void main(String args[])
{
    Student s1 = new Student(1, "Megha");
    Student s2 = new Student(2, "Monali", 20);
}
}

```

Comparing & Identifying Object

→ In Java, the `==` operator compares that two references are identical or not, whereas the `equals()` method compares two objects.

→ objects are equal when they have the same state. Objects are identical when they share the class identity.

eg `obj1 == obj2` (test identity)
`obj1.equals(obj2)` (compare equality)

Inheritance in Java:-

→ Inheritance in Java is a method mechanism in which one object acquires all the properties & behaviour of parent class.

→ The idea behind inheritance in Java is that you can create new classes that are built upon existing classes.

→ When we inherit from an existing class, we can reuse method & fields of the parent class. we can add new method

field in our current class.

→ Inheritance represents the IS-A relationship which is also known as Parent-child relationship.

Important terminology

i) Super class :-
The class whose features are inherited is known as Superclass (or base class / parent class).

ii) Sub class :-
The class that inherits the other class is known as subclass (or derived class / extended class / child class).

Syntax

The keyword used for inheritance is "extends".

↳ indicates that you are making a new class that derives from an existing class.

```
class childclass extends Parentclass
```

```
{
```

```
codes
```

```
}
```

```
class Parentclass
```

```
{
```

```
}
```

```
class childclass extends Parentclass
```

```
{
```

```
}
```

B.java

eg class A

```
{ int a=10, b=20;
```

```
}
```

```
class B extends A
```

```
{ public static void main(String args[]
```

```
{
```

```
int c=a+b;
```

```
System.out.println("The sum is: "+c);
```

```
}
```

```
}
```

Types of Inheritance:

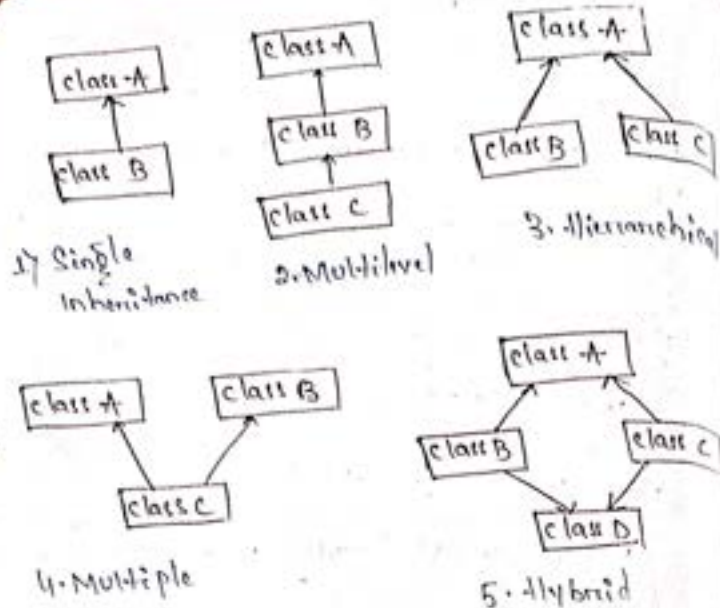

→ on the basis of class, there can be 3 types of inheritance in Java.

→ * Multiple & Hybrid inheritance (supported through interface only)

1. Single Inheritance

2. Multilevel Inheritance

3. ~~Hybrid~~ Hierarchical Inheritance

1. Single Inheritance:

When a (only 1 class) class inherits another class, it is known as single inheritance.

Syntax

```

public class A
{
    // ...
}

public class B extends A
{
    // ...
}
  
```

B.java

```

19 public class A
    {
        public void msg()
        {
            System.out.println("Hello");
        }
    }

    public class B extends A
    {
        public static void main(String args[])
        {
            public void display()
            {
                System.out.println("Good Morning");
                System.out.println("How are you?");
            }
            B ob = new B();
            ob.msg();
            ob.display();
        }
    }
  
```

2. Multilevel Inheritance

When there is a chain, it is called multilevel inheritance.

Syntax

```

public class A
{
    // ...
}

public class B extends A
{
    // ...
}

public class C extends B
{
    // ...
}
  
```

Z.java

```
class X
{
    public void ad myX()
    {
        System.out.println("X method");
    }
}
class Y extends X
{
    public void myY()
    {
        S.o.p("Y method");
    }
}
class Z extends Y
{
    public void mX()
    {
        System.out.println("Z method");
    }
}
public static void main(String args[])
{
    Z ob = new Z();
    ob.myX();
    ob.myY();
    ob.mX();
}
```

* Hierarchical class:

↳ one class is inherited by many subclasses
i.e. known as hierarchical class.

```
public class A { ... }
public class B extends A { ... }
public class C extends A { ... }
```

Z.java

```
class X
{
    public void myX()
    {
        S.o.p("X method");
    }
}
public class Y extends X
{
    public void myY()
    {
        S.o.p("Y method");
    }
}
public class Z extends X
{
    public void mX()
    {
        S.o.p("Z method");
    }
}
public static void main(String args[])
{
    Y ob = new Y();
    Z ob1 = new Z();
    ob.myX();
    ob.myY();
    ob1.mX();
    ob1.myY();
}
```

* Java does not support Multiple Inheritance.
This means that class ~~does not~~ can not
extend more than one class.

The Super keyword

→ The Super keyword is used to differentiate the members of Superclass/Parent class from the members of Subclass/Child class, if they have same name.

Differentiating the members

If a class is inheriting the properties of another class. And if the members of the Superclass have the same name as the Sub class, to differentiate these variables we use Super keyword.

1) Super-variables:

Super.method();

child.java

class Parent

{
int n = 10;

public void display()

{
System.out.println("this is Super class");
}

class child extends Parent

{
int n = 20;

public void display()

{
System.out.println("this is Sub class");

public void my-method()

~~public static void main(String args[])~~

child obj = new child();

obj.display();

obj.super.display();

S.O.P (obj.num);

S.O.P (super.num);

}

public static void main(String args[])

{

child obj = new child();

obj.my-method();

}

}

Note

1) Super can be used in method which is non-static.

2) In the above example Super is used in a non-static method named as my-method.

Polymorphism

It is an ability of an object to take on many forms.

1) int x = 10, y = 64;

System.out.println("x + y"); // 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32 33 34 35 36 37 38 39 40 41 42 43 44 45 46 47 48 49 50 51 52 53 54 55 56 57 58 59 60 61 62 63 64 65 66 67 68 69 70 71 72 73 74 75 76 77 78 79 80 81 82 83 84 85 86 87 88 89 90 91 92 93 94 95 96 97 98 99 100

System.out.println("x * y = " + x * y);

S.O.P ("x" = + x + "y" = + y);

Two types of polymorphism

a) compile Time polymorphism (static or Early Binding)

b) Run Time Dynamic or Late Binding or Dynamic Dispatching

a) Compile Time:

The object bind/call/invoke/associated with the appropriate method is already determined or decided prior to the compilation.

b) Run Time

The object bind/call/invoke/associate with the appropriate method is determined or decided at run time only.

2) class calculation

```
{
void add(int a, int b)
{
    System.out.println(a+b);
}
void add(int a, int b, int c)
{
    System.out.println(a+b+c);
}
public static void main(String args[])
{
}
```

calculation ob = new Calculation();

ob.add(10, 20, 30);

ob.add(20, 30);

}

}

→ There are 3 ways to achieve polymorphism

1. Overloading

2. Overriding

3. Interfacing

1. Method overloading

Multiple methods by same name but different parameters, is known as Method overloading.

→ compiler knows which method/function to call based on the parameter it is passed.

Why?

Suppose we have to perform addition of the given numbers but there can be any no. of arguments, if we write the method such as add2(int, int) bore two parameters and add3(int, int, int) bore 3 arguments then it may difficult

both programmers - to understand behaviour so we perform method overloading.

Two ways - to overload method

1. By changing number of arguments
2. By changing the data type

Note Method overloading is not possible by changing the return type of the method.

By changing no. of arguments

class calculation

```
{
void add(int a, int b)
{
    System.out.println(a+b);
}
void add(int a, int b, int c)
{
    System.out.println(a+b+c);
}
public static void main(String args[])
{
    calculation ob = new calculation();
    ob.add(10, 20);
    ob.add(10, 20, 30);
}
```

By changing datatype

class A

```
{
void add(int a, int b)
{
    System.out.println(a+b);
}
void add(double a, double b)
{
    System.out.println(a+b);
}
public static void main(String args[])
{
    A ob = new A();
    ob.add(10, 20);
    ob.add(10.5, 20.5);
}
```

2. Method overriding → Same name, Same Parameters
If subclass has the same name as the parent class is known as method overriding

Rules

1. Method must have same name as in the parent class.
2. Method must have same parameters as in the parent class.

```

eg class V
{
    void run()
    {
        S.O.P("inside parent class");
    }
}

class B extends V
{
    void run()
    {
        S.O.P("inside child class");
    }
}

public static void main(String args[])
{
    B obj1 = new B();
    obj1.run(); // B obj2 = new B();
                obj2.run();
}

```

Pass by value & Pass By Reference

→ Pass by value is also called call by value
 → Pass by Reference is also called call by Reference.

```

eg public class CB
{
    public void twobold(int n)
    {
        n = 2 * n;
        S.O.P("value inside twobold method = "
              + n); // 20
    }
    public void demo()
    {
        int x = 10;
        S.O.P("value before twobold method call = " + x);
        twobold(x); // 10
        S.O.P("value after twobold method = " + x);
        // 10
    }
}

```

Output

value before twobold method call = 10
 value inside twobold method = 20
 value after twobold method = 10

Call By Reference

Arguments are passed by reference rather than passing by value.

```

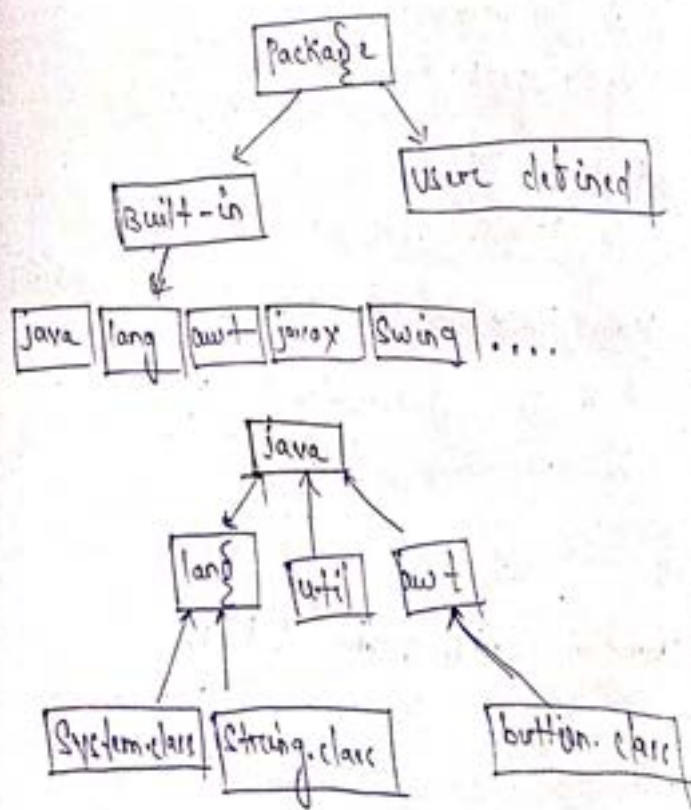

class callByRef
{
    static int x=1, y=2, s;
    public void sum()
    {
        S.o.p("original value" + x + " " + y);
    }
    s = x + y;
    S.o.p("original sum = " + s);
    callByRef ob = new callByRef();
    Test(ob);
    S.o.p("value after call" + x + " " + y);
}

public void Test(callByRef ob)
{
    callByRef.x = 100;
    callByRef.y = 200;
    int p = x * y;
    S.o.p("x * y = " + p);
}

```

JAVA PACKAGE

- Packages are used in java in order to prevent naming conflict, to control access, to make searching, locating & usage of classes, interfaces, enum etc easier.
- A package can be defined as a grouping of related types (classes, interfaces etc), providing access protection & namespace management.
- Package helps us to categorize our code in different folders.

→ The "package" keyword is used to create a package in java.

How to compile Java Package

javac -d directory javablename
switch -d specifies the destination where to put the generated class.

23 javac -d . Simple.java

→ # (.) package within the same directory

javac -d c:\Java\PK Simple.java

How to Run Java Package

java packagename.classname

java mypack.Simple Simple.java

package mypack;

public class Simple

{
public static void main(String args[])

{
System.out.println("welcome");

};
}

→ Changing drive from C to D
:\D:

How to Access Package from Another Package?

There are 3 ways to access package from outside the package.

1. import package.*;
2. import package.classname;
3. Fully Qualified name

Using Package Name:

If we use package.* then all the classes & interfaces of this package will be accessible but not sub package.

→ The import keyword is used to make classes & interfaces of another package accessible to the current package.

A.java

package testpack;

public class A

{
public void m1()

{
System.out.println("Hello");

};
}

B.java

package mypack;

import testpack.*;

public class B

{

```

public static void main(String args[])
{
    A ob = new A();
    ob.msg();
}

```

compile

F:\Java\PK> javac -d F:\Java\PK A.java
 F:\Java\PK> javac -d F:\Java\PK B.java
 F:\Java\PK> java mypack.B

2) Using package name.classname

If we import package name.classname only declared class of this package will be accessible.

eg:- A.java

```

package testpack;
public class A
{
    public void msg()
    {
        System.out.println("Hello");
    }
}

```

B.java

```

package mypack;
import testpack.A;
public class B
{

```

```

}
public static void main(String args[])
{
    A ob = new A();
    ob.msg();
}
}

```

3) Using Fully Qualified Name :

If we use fully qualified name then only declared class of this package will be accessible. Now there is no need to import.

A.java

```

package testpack;
public class A
{
    public void msg()
    {
        System.out.println("Hello");
    }
}

```

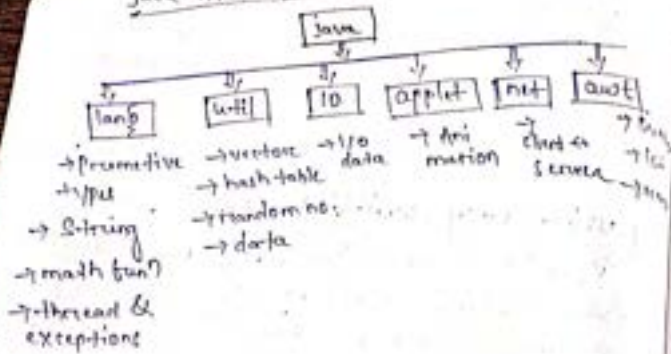

B.java

```

package mypack;
public class B
{
    public static void main(String args[])
    {
        testpack.A ob = new A();
        ob.msg();
    }
}

```

Java API Package

JVM (Java Virtual Machine) :

→ JVM is a specification that provides run-time environment in which java bytecode can be executed.

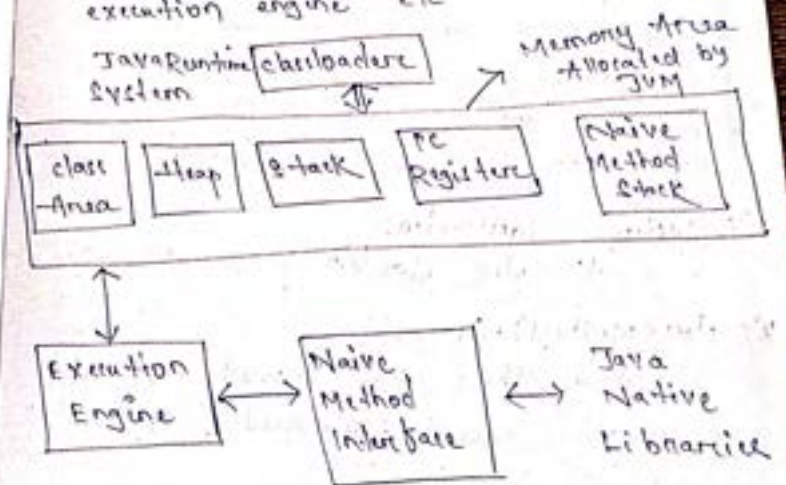

What it does ?

The JVM performs following operation

- Loads code
- Verifies code
- Executes code
- provides run-time environment

JVM Architecture

→ It contains classloader, memory area, execution engine etc

1) Class Loader:

It is a subsystem of JVM which is used to load class files.

→ Whenever we run the java program, it is loaded first by the classloader.

→ There are 3 built-in classloaders in Java.

a) Bootstrap classloader:

Super class of extension classloader.

→ It loads rt.jar file which contains all class files of java standard like java.lang, java.net, java.io, java.sql etc

b) Extension classloader:

This is the child classloader of Bootstrap & parent classloader of System classloader.

→ It loads the jar files located inside \$Java-HOME/jre/lib/ext directory

c) System classloader:

It loads class files from classpath.

2) Class (Method) Area:

Stores per-class structures such as runtime const. pool, field & method data, code block method.

3) Heap:

Run-time data area in which objects are allocated.

4) Stack:

It holds local variables & partial results, and plays a part in method invocation & return.

5) PC Register:

contains address of the JVM instruction currently being executed.

b) Native Method Stack:

It contains all the native methods used in the app.

4) Execution Engine:

It contains:

a) A virtual processor

b) Interpreter

c) JIT (Just-In-Time): JIT compile parts of the byte code that have similar funⁿ at the same time

8) Java Native Interface:

It is a framework which provides an interface to communicate with another appⁿ written in another language like C, C++ etc.

Exception Handling in JAVA

Error:

Errors are the wrong that make a program go wrong.

Compile-Time Errors:

Syntax errors at compile time because of

→ Missing Semicolons

class A

```
{  
    public static void main(String args[])
```

```
{  
    System.out.println("Hello");  
}
```

→ missing (or mismatch of) brackets in class & method body.

→ misspelling of identifiers & keywords

→ missing double quotes in strings

→ use of undeclared variable

→ incompatible types in assignment

→ Bad reference to object, ... etc

Reading Data from Keyboard

There are many ways to read data from keyboard. For example

a) `InputStreamReader`

b) `Scanner`

c) console/command line arguments

d) `DataInputStream`

`InputStreamReader` class:

It can be used to read data from keyboard.

→ It performs 2 tasks.

i) connect to input stream of keyboard

ii) converts the byte oriented stream into character-oriented stream

`BufferedReader` class:

It can also be used to read data line by line by `readLine()` method.

```
import java.io.*;
```

```
class A
```

```
{  
    public static void main(String args[])
```

```
{  
        InputStreamReader r = new InputStreamReader(  
            System.in);
```

```
        BufferedReader b = new BufferedReader(r);
```

```
        System.out.println("Enter your Name");
```

```
        String name = b.readLine();
```

```
        System.out.println(name);  
    }  
}
```

b) Java Scanner class:
There are various ways to read input from the keyboard, the java.util.Scanner class is one of them.

The Java Scanner class breaks the input into tokens using a delimiter that is whitespace by default.

commonly used method:
 2) public String next() :-
 It returns the next token from the Scanner.
 3) public void nextLine() :-

ii) `public String nextLine()` :-
It moves the Scanner position to the next line & returns the value as a String.

iv) `public int nextInt()` :-
It scans the next token as Integer

Long.
1) `public float nextFloat()`:-
It scans the next token as float.

vii) public double nextDouble():—
1. Scans the next token as double.

3 Java Scanner example with Delimiter (white space):

```
import java.util.*;
class SL
{
    public...
    {
        String input = "10 tea 20 coffee";
        Scanner sc = new Scanner(input);
        useDelimiter(" ");
        S.o.p(sc.nextInt());
        S.o.p(sc.nextInt());
        S.o.p(sc.nextInt());
        S.o.p(sc.nextInt());
        S.close();
    }
}
```

- Addition of 2 no.

```
import java.util.Scanner;
class Input
{
    public static void main(...)
    {
        Scanner sc = new Scanner(System.in);
        System.out.println("Enter 1st No.");
        int a = sc.nextInt();
        System.out.println("Enter 2nd No.");
        int b = sc.nextInt();
        int c = a + b;
        System.out.println(c);
    }
}
```

1) Command Line Argument as Input

Java main method consist array of String as main (String args[]). When we run the program, the array will be filled with the value of any arguments through command line.

→ Each element in an array can be referred or accessed by an array name & index (a[0]).

eg c: > javac -A.java

c: > java -A 1 2 3

Here command line contains 3 arguments

```
a[0] 1
a[1] 2
a[2] 3
```

```
13 class -A
{
    public static void main(String args[])
    {
        System.out.println("Hello");
        System.out.println(a[0]);
    }
}
```

compile :- c: > javac -A.java

Run :- c: > java -A Monali

o/p Hello Monali

```
class -A
{
    public static void main(String args[])
    {
        int i = 0;
        for (i = 0; i < a.length; i++)
        {
            System.out.println(a[i]);
        }
    }
}
```

Java IO :-

Java IO (input & output) is used to process the input & produce the output.

→ The java.io package contains all the classes required for input & output operations.

Stream

A stream is a sequence of data.

→ In java, a stream is composed of bytes. It's called a stream because it is like stream of water that continues to flow.

→ In java 3 streams are created for us automatically.

1) System.out: Standard output stream

2) System.in: Standard input stream

3) System.err: Standard error stream

eg `System.out.println("Simple Message!");`

`System.err.println("error Message!");`

`int i = System.in.read();`

`System.out.println(char i);`

OutputStream

Java appⁿ use an output stream to write data to a destination.

→ It may be a file, an array, peripheral device.

Input Stream

Java appⁿ uses an input stream to read data from a source; it may be a file.

OutputStream class

It is the superclass of all classes representing an output stream of byte.

→ An output stream accepts output bytes & sends them to some sink.

Useful Methods of OutputStream

Method	Description
1) <code>public void write(int)</code> throws <code>IOException</code>	Is used to write a byte to the current output stream
2) <code>public void write(byte[])</code> throws <code>IOException</code>	Is used to write an array of byte to the current output stream
3) <code>public void flush()</code> throws <code>IOException</code>	Flushes the current output stream
4) <code>public void close()</code> throws <code>IOException</code>	Is used to close the current output stream

InputStream class:

→ It is the superclass of all classes representing an input stream of bytes.
Useful methods of InputStream

Method	Description
1) public abstract int read()	Reads the next byte of data from the input stream. If no byte is available, it returns -1 at the end of the file.

2) public int available()	Returns an estimate of the number of bytes that can be read from the current input stream.
---------------------------	--

3) public void close() throws IOException	Is used to close the current input stream.
---	--

Java FileOutputStream class:-

Java FileOutputStream is an output stream used for writing data to a file.
(write byte)

```

import java.io.*;
public class FileOutputExample {
    public static void main (String args[]) {
        try {
            // ...
        }
    }
}
    
```

```

FileOutputStream fout = new FileOutputStream(
    "D:\\t1.txt");
    
```

location of the file

```

fout.write(b5);
fout.close();
System.out.println("Success!");
} catch (Exception e) {
    System.out.println(e);
}
}
}
    
```

-4

Write String

```

import java.io.*;
public class FileExample {
    public static void main (String args[]) {
        try {
            FileOutputStream fout = new FileOutputStream(
                "D:\\t1.txt");
            String s = "welcome to my file";
            byte[] b = s.getBytes();
            fout.write(b);
            fout.close();
            System.out.println("Success!");
        }
    }
}
    
```

```

    catch (Exception e) {
        System.out.println(e);
    }
}

```

Java FileInputStream class

Java FileInputStream class obtains input bytes from a file.

Java FileInputStream class Methods

Method	Description
int available()	It is used to return the estimated no. of bytes that can be read from the input stream.
int read()	It is used to read the byte of data from the input stream.
int read(byte[] b)	It is used to read up to b.length bytes of data from the input stream.
void close()	It is used to close the stream.

39. Read single characters

```

import java.io.*;
public class DataStreamEX {
    public static void main (String args[]) {
        try {
            FileInputStream fin = new FileInputStream(
                "D:\\U-1X4");

            int i = fin.read();
            System.out.println((char)i);
            fin.close();
        } catch (Exception e) {
            System.out.println(e);
        }
    }
}

```

40. Read all characters

```

import java.io.*;
public class A {
    public static void main (String args[]) {
        try {
            new
            FileInputStream fin = new FileInputStream("D:\\U-1X4");

            int i = 0;

```

```

catch (Exception e)
{
    System.out.println(e);
}
}
}

```

Java FileInputStream class

Java FileInputStream class obtains input bytes from a file.

Java FileInputStream class Methods

Method

Description

int available()

It is used to return the estimated no. of bytes that can be read from the input stream.

int read()

It is used to read the byte of data from the input stream.

int read(byte[] b)

It is used to read up to b.length bytes of data from the input stream.

void close()

It is used to close the stream.

eg Read Single character

```

import java.io.FileInputStream;
public class DataStreamEX
{
    public static void main (String args[])
    {
        try
        {
            FileInputStream fin = new FileInputStream(
                "D:\\U-EX.txt");

            int i = fin.read();
            System.out.println((char)i);
            fin.close();
        }
        catch (Exception e)
        {
            System.out.println(e);
        }
    }
}

```

eg Read all characters

```

import java.io.FileInputStream;
public class A
{
    public static void main (String args[])
    {
        try
        {
            new
            FileInputStream fin = new FileInputStream(
                "D:\\U-EX.txt");

            int i = 0;

```

```

while(c != fin.read() != -1)
{
    System.out.println(c);
}
fin.close();
}
catch (Exception e)
{
    System.out.println(e);
}
}
}

```

File Handling in Java

→ In Java, File Handling is done with the help of the File class of the java.io package.

File Handling operation

1. Creating a new file
2. Writing in a file
3. Reading an existing file
4. Deleting a file

→ To perform any of the above operations on a file in java, we need to create an object of the File classes

```

import java.io.File;
File obj = new File("Filename.txt");

```

↳ Specify the name of the file

1. Creating a New file :

```

import java.io.File;
import java.io.FileHandler;
public class CNF
{
    public static void main (String args[])
    {
        File ob = new File("abc.txt");
        try
        {
            ob.createNewFile();
            S.O.p.c "Successfull";
        }
    }
}

```

```
catch (IOException e)
```

```
{
    S.O.P(e);
}
```

→ To create a file in java, you can use the `createNewFile()` method.
 → This method returns a boolean value i.e. T/F. (The method is enclosed in a try... catch)

2. Write to a file

→ We use `FileWriter` (it is used to write characters-oriented data to a file) class together with its `write()` method. Write some text to the file we created.

→ You should close it with the `close()` method.

```
import java.io.*;
import java.io.IOException;

public class WriteToFile {
    public static void main (String args[]) {
        try {
            FileWriter fo = new FileWriter("at.txt");
```

```
fo.write("Thicky but not enough");
fo.close();
```

```
S.O.P("Successfull");
```

```
catch (IOException e)
```

```
{
    S.O.P("Error");
```

```
    e.printStackTrace();
}
```

3. Read a file :-

We use the `Scanner` class to read the contents of the file

```
import java.io.*;
import java.io.FileNotFoundException;
import java.util.Scanner;

public class ReadFile {
    public static void main (String args[]) {
        try {
            File obj = new File("at.txt");
            Scanner myReader = new Scanner(obj);
            while (myReader.hasNextLine()) {
                String data = myReader.nextLine();
                S.O.P(data);
            }
        }
    }
}
```

```

        myReader.close();
    } catch (FileNotFoundException e)
    {
        S.o.p("Error");
        e.printStackTrace();
    }
}
}

```

4. Deleting file :-

To delete a file, use the delete() method

```

19 import java.io.*;
public class DeleteFile
{
    public static void main (String args[])
    {
        File obj = new File ("a1.txt");
        if (obj.delete())
        {
            S.o.p("Deleted file : " + obj.getName());
        }
        else
        {
            S.o.p("Failed to delete the file");
        }
    }
}

```
